#### Understanding **Embedded - FPGAs (Field Programmable Gate Array)**

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

#### **Applications of Embedded - FPGAs**

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

**Notes:**

1. Typical values are specified at nominal voltage, 85°C junction temperatures (T<sub>j</sub>) with single-ended SelectIO resources.
2. Typical values are for blank configured devices with no output current loads, no active input pull-up resistors, all I/O pins are 3-state and floating.
3. Use the Xilinx Power Estimator (XPE) spreadsheet tool (download at <http://www.xilinx.com/power>) to calculate static power consumption for conditions other than those specified.

**Table 7** shows the minimum current, in addition to  $I_{CCQ}$ , that is required by Virtex-7 T and XT devices for proper power-on and configuration. If the current minimums shown in **Table 6** and **Table 7** are met, the device powers on after all five supplies have passed through their power-on reset threshold voltages. The FPGA must not be configured until after  $V_{CCINT}$  is applied.

Once initialized and configured, use the XPower tools to estimate current drain on these supplies.

These parameters do not apply to the BUFGMUX primitive that assures glitch-free operation. The other global clock setup and hold times are optional; only needing to be satisfied if device operation requires simulation matches on a cycle-for-cycle basis when switching between clocks.
2. T<sub>BGCKO\_O</sub> (BUFG delay from I0 to O) values are the same as T<sub>BCCKO\_O</sub> values.

**Notes:**

1. The MMCM does not filter typical spread-spectrum input clocks because they are usually far below the bandwidth filter frequencies.
2. The static offset is measured between any MMCM outputs with identical phase.
3. Values for this parameter are available in the Clocking Wizard.  
See [http://www.xilinx.com/products/intellectual-property/clocking\\_wizard.htm](http://www.xilinx.com/products/intellectual-property/clocking_wizard.htm).
4. Includes global clock buffer.
5. Calculated as  $F_{VCO}/128$  assuming output duty cycle is 50%.
6. When CLKOUT4\_CASCADE = TRUE, MMCM\_F\_OUTMIN is 0.036 MHz.
