Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details

Product Status	Obsolete
Number of LABs/CLBs	-
Number of Logic Elements/Cells	-
Total RAM Bits	36864
Number of I/O	65
Number of Gates	250000
Voltage - Supply	1.425V ~ 1.575V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 100°C (TJ)
Package / Case	180-WFQFN Dual Rows, Exposed Pad
Supplier Device Package	180-QFN (10x10)
Purchase URL	https://www.e-xfl.com/product-detail/microsemi/m1afs250-qng180i

Instant On

Flash-based Fusion devices are Level 0 Instant On. Instant On Fusion devices greatly simplify total system design and reduce total system cost by eliminating the need for CPLDs. The Fusion Instant On clocking (PLLs) replaces off-chip clocking resources. The Fusion mix of Instant On clocking and analog resources makes these devices an excellent choice for both system supervisor and system management functions. Instant On from a single 3.3 V source enables Fusion devices to initiate, control, and monitor multiple voltage supplies while also providing system clocks. In addition, glitches and brownouts in system power will not corrupt the Fusion device flash configuration. Unlike SRAM-based FPGAs, the device will not have to be reloaded when system power is restored. This enables reduction or complete removal of expensive voltage monitor and brownout detection devices from the PCB design. Flash-based Fusion devices simplify total system design and reduce cost and design risk, while increasing system reliability.

Firm Errors

Firm errors occur most commonly when high-energy neutrons, generated in the upper atmosphere, strike a configuration cell of an SRAM FPGA. The energy of the collision can change the state of the configuration cell and thus change the logic, routing, or I/O behavior in an unpredictable way. Another source of radiation-induced firm errors is alpha particles. For an alpha to cause a soft or firm error, its source must be in very close proximity to the affected circuit. The alpha source must be in the package molding compound or in the die itself. While low-alpha molding compounds are being used increasingly, this helps reduce but does not entirely eliminate alpha-induced firm errors.

Firm errors are impossible to prevent in SRAM FPGAs. The consequence of this type of error can be a complete system failure. Firm errors do not occur in Fusion flash-based FPGAs. Once it is programmed, the flash cell configuration element of Fusion FPGAs cannot be altered by high-energy neutrons and is therefore immune to errors from them.

Recoverable (or soft) errors occur in the user data SRAMs of all FPGA devices. These can easily be mitigated by using error detection and correction (EDAC) circuitry built into the FPGA fabric.

Low Power

Flash-based Fusion devices exhibit power characteristics similar to those of an ASIC, making them an ideal choice for power-sensitive applications. With Fusion devices, there is no power-on current surge and no high current transition, both of which occur on many FPGAs.

Fusion devices also have low dynamic power consumption and support both low power standby mode and very low power sleep mode, offering further power savings.

Advanced Flash Technology

The Fusion family offers many benefits, including nonvolatility and reprogrammability through an advanced flash-based, 130-nm LVCMOS process with seven layers of metal. Standard CMOS design techniques are used to implement logic and control functions. The combination of fine granularity, enhanced flexible routing resources, and abundant flash switches allows very high logic utilization (much higher than competing SRAM technologies) without compromising device routability or performance. Logic functions within the device are interconnected through a four-level routing hierarchy.

Advanced Architecture

The proprietary Fusion architecture provides granularity comparable to standard-cell ASICs. The Fusion device consists of several distinct and programmable architectural features, including the following (Figure 1-1 on page 1-5):

- Embedded memories
 - Flash memory blocks
 - FlashROM
 - SRAM and FIFO
- Clocking resources
 - PLL and CCC
 - RC oscillator
 - Crystal oscillator
 - No-Glitch MUX (NGMUX)
- Digital I/Os with advanced I/O standards
- FPGA VersaTiles
- Analog components
 - ADC
 - Analog I/Os supporting voltage, current, and temperature monitoring
 - 1.5 V on-board voltage regulator
 - Real-time counter

The FPGA core consists of a sea of VersaTiles. Each VersaTile can be configured as a three-input logic lookup table (LUT) equivalent or a D-flip-flop or latch (with or without enable) by programming the appropriate flash switch interconnections. This versatility allows efficient use of the FPGA fabric. The VersaTile capability is unique to the Microsemi families of flash-based FPGAs. VersaTiles and larger functions are connected with any of the four levels of routing hierarchy. Flash switches are distributed throughout the device to provide nonvolatile, reconfigurable interconnect programming. Maximum core utilization is possible for virtually any design.

In addition, extensive on-chip programming circuitry allows for rapid (3.3 V) single-voltage programming of Fusion devices via an IEEE 1532 JTAG interface.

Unprecedented Integration

Integrated Analog Blocks and Analog I/Os

Fusion devices offer robust and flexible analog mixed signal capability in addition to the high-performance flash FPGA fabric and flash memory block. The many built-in analog peripherals include a configurable 32:1 input analog MUX, up to 10 independent MOSFET gate driver outputs, and a configurable ADC. The ADC supports 8-, 10-, and 12-bit modes of operation with a cumulative sample rate up to 600 k samples per second (Ksps), differential nonlinearity (DNL) < 1.0 LSB, and Total Unadjusted Error (TUE) of 0.72 LSB in 10-bit mode. The TUE is used for characterization of the conversion error and includes errors from all sources, such as offset and linearity. Internal bandgap circuitry offers 1% voltage reference accuracy with the flexibility of utilizing an external reference voltage. The ADC channel sampling sequence and sampling rate are programmable and implemented in the FPGA logic using Designer and Libero SoC software tool support.

Two channels of the 32-channel ADCMUX are dedicated. Channel 0 is connected internally to VCC and can be used to monitor core power supply. Channel 31 is connected to an internal temperature diode which can be used to monitor device temperature. The 30 remaining channels can be connected to external analog signals. The exact number of I/Os available for external connection signals is device-dependent (refer to the "Fusion Family" table on page I for details).

Global Clocking

Fusion devices have extensive support for multiple clocking domains. In addition to the CCC and PLL support described above, there are on-chip oscillators as well as a comprehensive global clock distribution network.

The integrated RC oscillator generates a 100 MHz clock. It is used internally to provide a known clock source to the flash memory read and write control. It can also be used as a source for the PLLs.

The crystal oscillator supports the following operating modes:

- Crystal (32.768 KHz to 20 MHz)
- Ceramic (500 KHz to 8 MHz)
- RC (32.768 KHz to 4 MHz)

Each VersaTile input and output port has access to nine VersaNets: six main and three quadrant global networks. The VersaNets can be driven by the CCC or directly accessed from the core via MUXes. The VersaNets can be used to distribute low-skew clock signals or for rapid distribution of high-fanout nets.

Digital I/Os with Advanced I/O Standards

The Fusion family of FPGAs features a flexible digital I/O structure, supporting a range of voltages (1.5 V, 1.8 V, 2.5 V, and 3.3 V). Fusion FPGAs support many different digital I/O standards, both single-ended and differential.

The I/Os are organized into banks, with four or five banks per device. The configuration of these banks determines the I/O standards supported. The banks along the east and west sides of the device support the full range of I/O standards (single-ended and differential). The south bank supports the Analog Quads (analog I/O). In the family's two smaller devices, the north bank supports multiple single-ended digital I/O standards. In the family's larger devices, the north bank is divided into two banks of digital Pro I/Os, supporting a wide variety of single-ended, differential, and voltage-referenced I/O standards.

Each I/O module contains several input, output, and enable registers. These registers allow the implementation of the following applications:

- Single-Data-Rate (SDR) applications
- Double-Data-Rate (DDR) applications—DDR LVDS I/O for chip-to-chip communications
- Fusion banks support LVPECL, LVDS, BLVDS, and M-LVDS with 20 multi-drop points.

VersaTiles

The Fusion core consists of VersaTiles, which are also used in the successful ProASIC3 family. The Fusion VersaTile supports the following:

- All 3-input logic functions—LUT-3 equivalent
- Latch with clear or set
- D-flip-flop with clear or set and optional enable

Refer to [Figure 1-2](#) for the VersaTile configuration arrangement.

Figure 1-2 • VersaTile Configurations

Figure 2-10 • Very-Long-Line Resources

Flash Memory Block Addressing

Figure 2-34 shows a graphical representation of the flash memory block.

Figure 2-34 • Flash Memory Block Organization

Each FB is partitioned into sectors, pages, blocks, and bytes. There are 64 sectors in an FB, and each sector contains 32 pages and 1 spare page. Each page contains 8 data blocks and 1 auxiliary block. Each data block contains 16 bytes of user data, and the auxiliary block contains 4 bytes of user data.

Addressing for the FB is shown in Table 2-20.

Table 2-20 • FB Address Bit Allocation ADDR[17:0]

17	12	11	7	6	4	3	0
Sector		Page		Block		Byte	

When the spare page of a sector is addressed (SPAREPAGE active), ADDR[11:7] are ignored.

When the Auxiliary block is addressed (AUXBLOCK active), ADDR[6:2] are ignored.

Note: The spare page of sector 0 is unavailable for any user data. Writes to this page will return an error, and reads will return all zeroes.

Flash Memory Block Characteristics

Figure 2-44 • Reset Timing Diagram

Table 2-25 • Flash Memory Block Timing
Commercial Temperature Range Conditions: $T_J = 70^{\circ}\text{C}$, Worst-Case $V_{CC} = 1.425\text{ V}$

Parameter	Description	-2	-1	Std.	Units
t_{CLK2RD}	Clock-to-Q in 5-cycle read mode of the Read Data	7.99	9.10	10.70	ns

Conversely, when writing 4-bit values and reading 9-bit values, the ninth bit of a read operation will be undefined. The RAM blocks employ little-endian byte order for read and write operations.

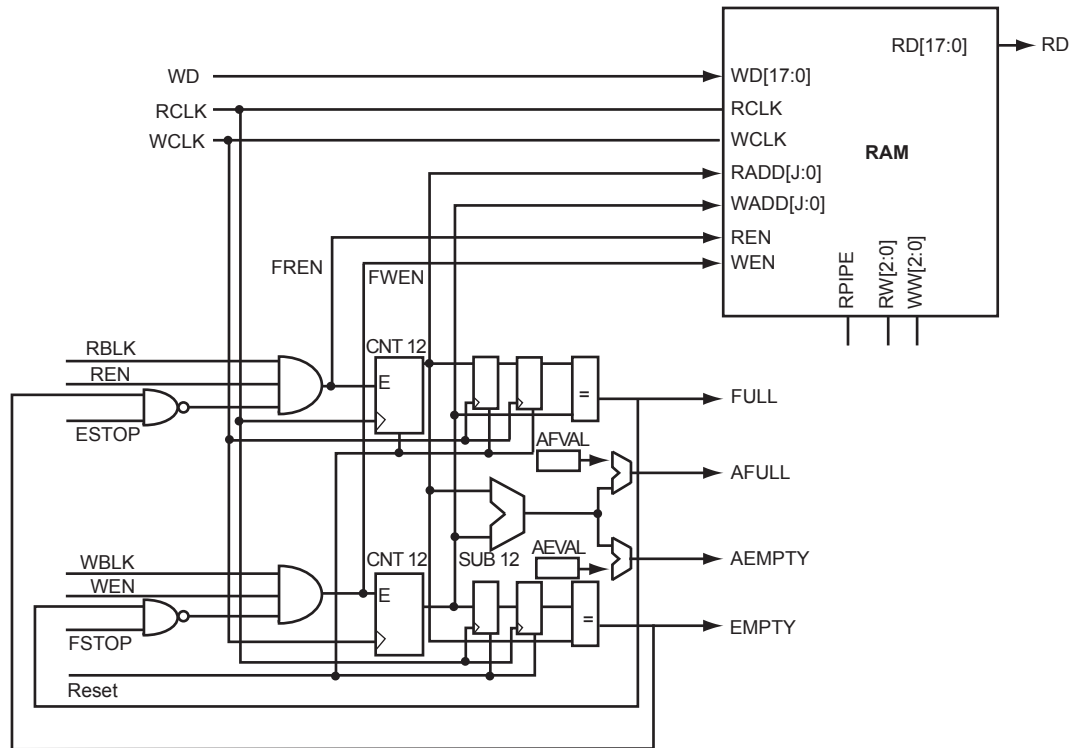

Figure 2-47 • Fusion RAM Block with Embedded FIFO Controller

Analog Block

With the Fusion family, Microsemi has introduced the world's first mixed-mode FPGA solution. Supporting a robust analog peripheral mix, Fusion devices will support a wide variety of applications. It is this Analog Block that separates Fusion from all other FPGA solutions on the market today.

By combining both flash and high-speed CMOS processes in a single chip, these devices offer the best of both worlds. The high-performance CMOS is used for building RAM resources. These high-performance structures support device operation up to 350 MHz. Additionally, the advanced Microsemi 0.13 μm flash process incorporates high-voltage transistors and a high-isolation, triple-well process. Both of these are suited for the flash-based programmable logic and nonvolatile memory structures.

High-voltage transistors support the integration of analog technology in several ways. They aid in noise immunity so that the analog portions of the chip can be better isolated from the digital portions, increasing analog accuracy. Because they support high voltages, Microsemi flash FPGAs can be connected directly to high-voltage input signals, eliminating the need for external resistor divider networks, reducing component count, and increasing accuracy. By supporting higher internal voltages, the Microsemi advanced flash process enables high dynamic range on analog circuitry, increasing precision and signal-noise ratio. Microsemi flash FPGAs also drive high-voltage outputs, eliminating the need for external level shifters and drivers.

The unique triple-well process enables the integration of high-performance analog features with increased noise immunity and better isolation. By increasing the efficiency of analog design, the triple-well process also enables a smaller overall design size, reducing die size and cost.

The Analog Block consists of the Analog Quad I/O structure, RTC (for details refer to the ["Real-Time Counter System" section on page 2-31](#)), ADC, and ACM. All of these elements are combined in the single Analog Block macro, with which the user implements this functionality ([Figure 2-64](#)).

The Analog Block needs to be reset/reinitialized after the core powers up or the device is programmed. An external reset/initialize signal, which can come from the internal voltage regulator when it powers up, must be applied.

Typical scaling factors are given in [Table 2-57 on page 2-130](#), and the gain error (which contributes to the minimum and maximum) is in [Table 2-49 on page 2-117](#).

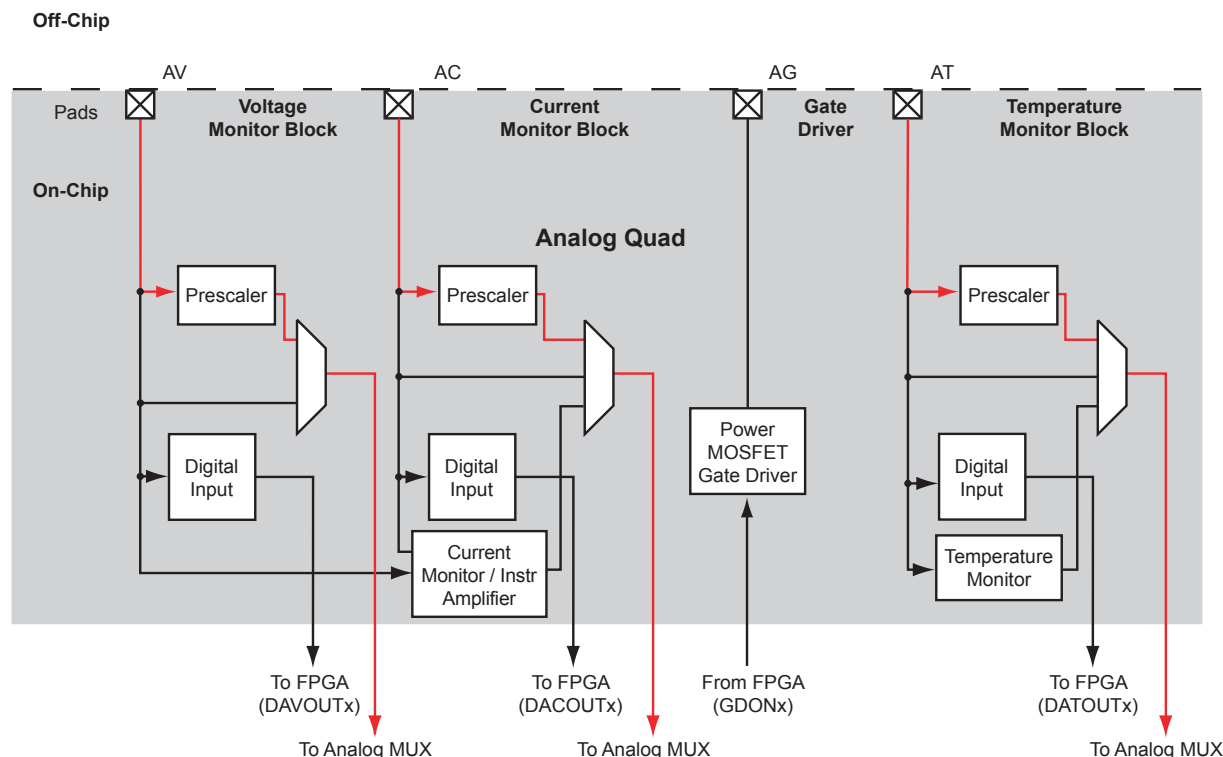

Figure 2-67 • Analog Quad Prescaler Input Configuration

Terminology

BW – Bandwidth

BW is a range of frequencies that a Channel can handle.

Channel

A channel is define as an analog input configured as one of the Prescaler range shown in [Table 2-57 on page 2-130](#). The channel includes the Prescaler circuit and the ADC.

Channel Gain

Channel Gain is a measured of the deviation of the actual slope from the ideal slope. The slope is measured from the 20% and 80% point.

$$\text{Gain} = \frac{\text{Gain}_{\text{actual}}}{\text{Gain}_{\text{ideal}}}$$

EQ 1

Channel Gain Error

Channel Gain Error is a deviation from the ideal slope of the transfer function. The Prescaler Gain Error is expressed as the percent difference between the actual and ideal, as shown in [EQ 2](#).

$$\text{Error}_{\text{Gain}} = (1 - \text{Gain}) \times 100\%$$

EQ 2

TUE – Total Unadjusted Error

TUE is a comprehensive specification that includes linearity errors, gain error, and offset error. It is the worst-case deviation from the ideal device performance. TUE is a static specification (Figure 2-87).

Figure 2-87 • Total Unadjusted Error (TUE)

ADC Operation

Once the ADC has powered up and been released from reset, ADCRESET, the ADC will initiate a calibration routine designed to provide optimal ADC performance. The Fusion ADC offers a robust calibration scheme to reduce integrated offset and linearity errors. The offset and linearity errors of the main capacitor array are compensated for with an 8-bit calibration capacitor array. The offset/linearity error calibration is carried out in two ways. First, a power-up calibration is carried out when the ADC comes out of reset. This is initiated by the CALIBRATE output of the Analog Block macro and is a fixed number of ADC_CLK cycles (3,840 cycles), as shown in Figure 2-89 on page 2-111. In this mode, the linearity and offset errors of the capacitors are calibrated.

To further compensate for drift and temperature-dependent effects, every conversion is followed by post-calibration of either the offset or a bit of the main capacitor array. The post-calibration ensures that, over time and with temperature, the ADC remains consistent.

After both calibration and the setting of the appropriate configurations, as explained above, the ADC is ready for operation. Setting the ADCSTART signal high for one clock period will initiate the sample and conversion of the analog signal on the channel as configured by CHNUMBER[4:0]. The status signals SAMPLE and BUSY will show when the ADC is sampling and converting (Figure 2-91 on page 2-112). Both SAMPLE and BUSY will initially go high. After the ADC has sampled and held the analog signal, SAMPLE will go low. After the entire operation has completed and the analog signal is converted, BUSY will go low and DATAVALID will go high. This indicates that the digital result is available on the RESULT[11:0] pins.

DATAVALID will remain high until a subsequent ADCSTART is issued. The DATAVALID goes low on the rising edge of SYSCLK as shown in Figure 2-90 on page 2-112. The RESULT signals will be kept constant until the ADC finishes the subsequent sample. The next sampled RESULT will be available when DATAVALID goes high again. It is ideal to read the RESULT when DATAVALID is '1'. The RESULT is latched and remains unchanged until the next DATAVALID rising edge.

Integrated Voltage Reference

The Fusion device has an integrated on-chip 2.56 V reference voltage for the ADC. The value of this reference voltage was chosen to make the prescaling and postscaling factors for the prescaler blocks change in a binary fashion. However, if desired, an external reference voltage of up to 3.3 V can be connected between the VAREF and ADCGNDREF pins. The VAREFSEL control pin is used to select the reference voltage.

Table 2-42 • VAREF Bit Function

Name	Bit	Function
VAREF	0	Reference voltage selection 0 – Internal voltage reference selected. VAREF pin outputs 2.56 V. 1 – Input external voltage reference from VAREF and ADCGNDREF

ADC Clock

The speed of the ADC depends on its internal clock, ADCCLK, which is not accessible to users. The ADCCLK is derived from SYSCLK. Input signal TVC[7:0], Time Divider Control, determines the speed of the ADCCLK in relationship to SYSCLK, based on [EQ 15](#).

$$t_{\text{ADCCLK}} = 4 \times (1 + \text{TVC}) \times t_{\text{SYSCLK}}$$

EQ 15

TVC: Time Divider Control (0–255)

t_{ADCCLK} is the period of ADCCLK, and must be between 0.5 MHz and 10 MHz

t_{SYSCLK} is the period of SYSCLK

Table 2-43 • TVC Bits Function

Name	Bits	Function
TVC	[7:0]	SYSCLK divider control

The frequency of ADCCLK, f_{ADCCLK} , must be within 0.5 Hz to 10 MHz.

The inputs to the ADC are synchronized to SYSCLK. A conversion is initiated by asserting the ADCSTART signal on a rising edge of SYSCLK. [Figure 2-90 on page 2-112](#) and [Figure 2-91 on page 2-112](#) show the timing diagram for the ADC.

Acquisition Time or Sample Time Control

Acquisition time (t_{SAMPLE}) specifies how long an analog input signal has to charge the internal capacitor array. [Figure 2-88](#) shows a simplified internal input sampling mechanism of a SAR ADC.

Figure 2-88 • Simplified Sample and Hold Circuitry

The internal impedance (Z_{INAD}), external source resistance (R_{SOURCE}), and sample capacitor (C_{INAD}) form a simple RC network. As a result, the accuracy of the ADC can be affected if the ADC is given insufficient time to charge the capacitor. To resolve this problem, you can either reduce the source resistance or increase the sampling time by changing the acquisition time using the STC signal.

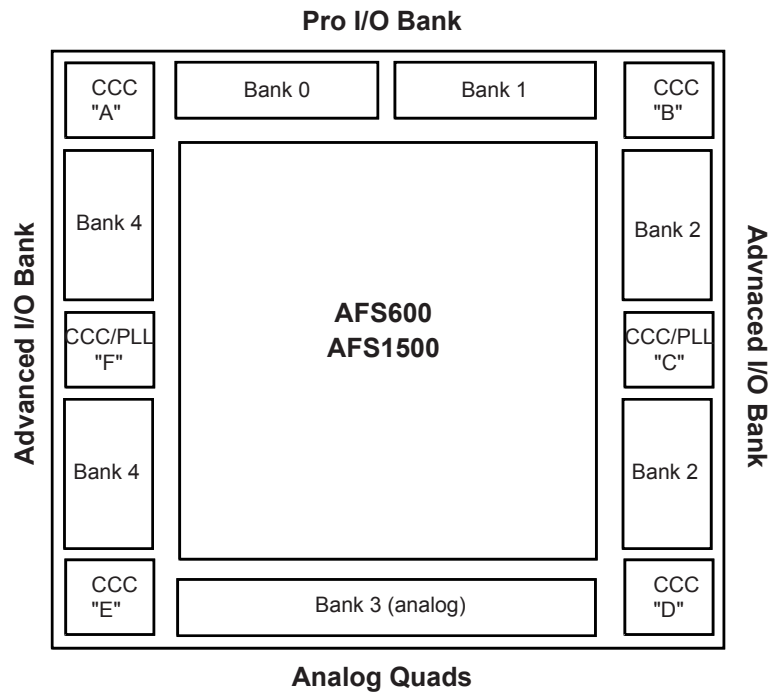

Figure 2-114 • Naming Conventions of Fusion Devices with Four I/O Banks

Table 2-88 • Summary of Maximum and Minimum DC Input and Output Levels Applicable to Commercial and Industrial Conditions
Applicable to Standard I/Os

I/O Standard	Drive Strength	Slew Rate	VIL		VIH		VOL	VOH	IOL	IOH
			Min. V	Max. V	Min. V	Max. V	Max. V	Min. V	mA	mA
3.3 V LVTTTL / 3.3 V LVCMOS	8 mA	High	-0.3	0.8	2	3.6	0.4	2.4	8	8
2.5 V LVCMOS	8 mA	High	-0.3	0.7	1.7	3.6	0.7	1.7	8	8

HSTL Class I

High-Speed Transceiver Logic is a general-purpose high-speed 1.5 V bus standard (EIA/JESD8-6). Fusion devices support Class I. This provides a differential amplifier input buffer and a push-pull output buffer.

Table 2-150 • Minimum and Maximum DC Input and Output Levels

HSTL Class I	VIL		VIH		VOL	VOH	IOL	IOH	IOSL	IOSH	IIL ¹	IIH ²
Drive Strength	Min. V	Max. V	Min. V	Max. V	Max. V	Min. V	mA	mA	Max. mA ³	Max. mA ³	μA ⁴	μA ⁴
8 mA	−0.3	VREF − 0.1	VREF + 0.1	3.6	0.4	VCCI − 0.4	8	8	39	32	10	10

Notes:

1. IIL is the input leakage current per I/O pin over recommended operation conditions where $-0.3\text{ V} < V_{IN} < V_{IL}$.
2. IIH is the input leakage current per I/O pin over recommended operating conditions $V_{IH} < V_{IN} < V_{CCI}$. Input current is larger when operating outside recommended ranges.
3. Currents are measured at high temperature (100°C junction temperature) and maximum voltage.
4. Currents are measured at 85°C junction temperature.

Figure 2-128 • AC Loading

Table 2-151 • AC Waveforms, Measuring Points, and Capacitive Loads

Input Low (V)	Input High (V)	Measuring Point* (V)	VREF (typ.) (V)	VTT (typ.) (V)	C _{LOAD} (pF)
VREF − 0.1	VREF + 0.1	0.75	0.75	0.75	20

Note: *Measuring point = V_{trip} . See Table 2-90 on page 2-166 for a complete table of trip points.

Timing Characteristics

Table 2-152 • HSTL Class I

Commercial Temperature Range Conditions: $T_J = 70^\circ\text{C}$, Worst-Case VCC = 1.425 V, Worst-Case VCCI = 1.4 V, VREF = 0.75 V

Speed Grade	t _{DOUT}	t _{DP}	t _{DIN}	t _{PY}	t _{EOUT}	t _{ZL}	t _{ZH}	t _{LZ}	t _{HZ}	t _{ZLS}	t _{ZHS}	Units
Std.	0.66	3.18	0.04	2.12	0.43	3.24	3.14			5.47	5.38	ns
−1	0.56	2.70	0.04	1.81	0.36	2.75	2.67			4.66	4.58	ns
−2	0.49	2.37	0.03	1.59	0.32	2.42	2.35			4.09	4.02	ns

Note: For the derating values at specific junction temperature and voltage supply levels, refer to Table 3-7 on page 3-9.

Fully Registered I/O Buffers with Synchronous Enable and Asynchronous Clear

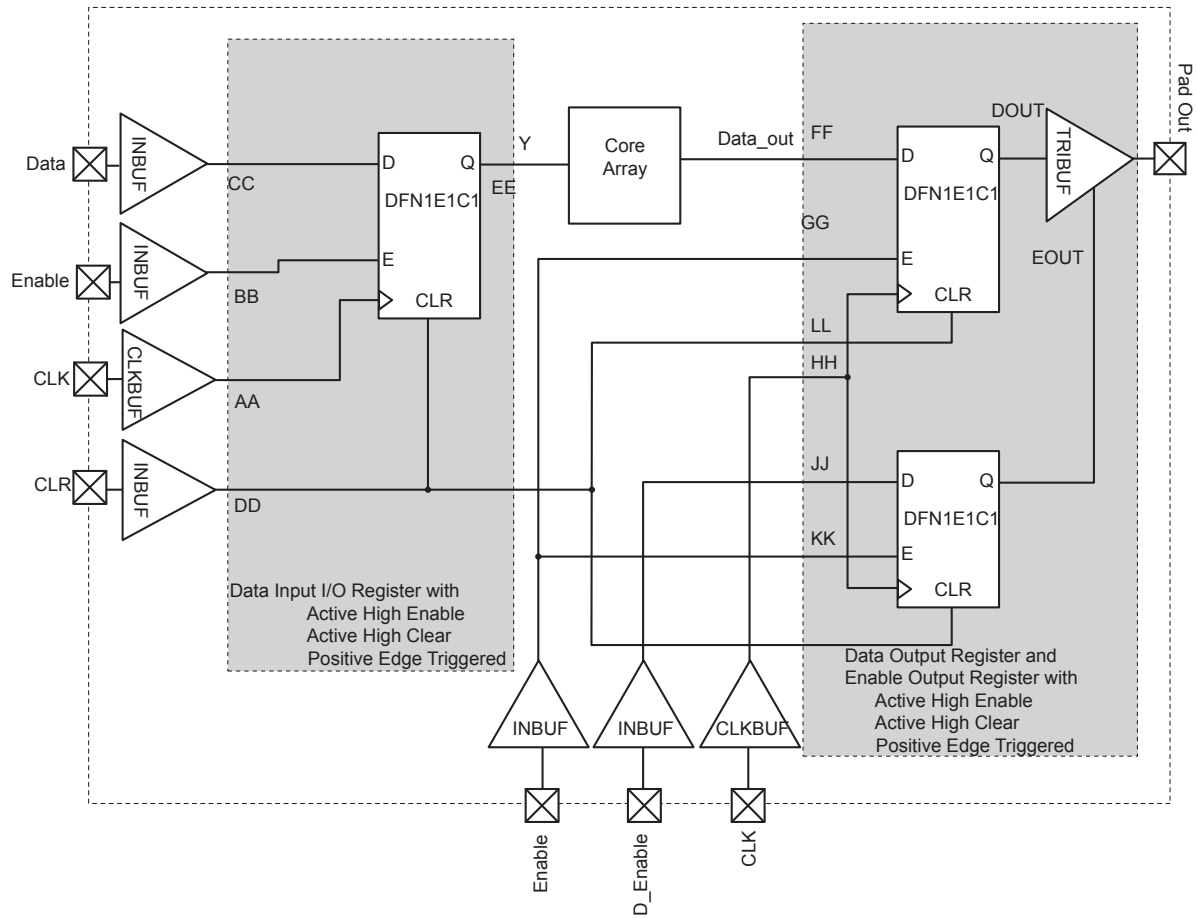

Figure 2-138 • Timing Model of the Registered I/O Buffers with Synchronous Enable and Asynchronous Clear

TMS Test Mode Select

The TMS pin controls the use of the IEEE1532 boundary scan pins (TCK, TDI, TDO, TRST). There is an internal weak pull-up resistor on the TMS pin.

TRST Boundary Scan Reset Pin

The TRST pin functions as an active low input to asynchronously initialize (or reset) the boundary scan circuitry. There is an internal weak pull-up resistor on the TRST pin. If JTAG is not used, an external pull-down resistor could be included to ensure the TAP is held in reset mode. The resistor values must be chosen from [Table 2-183](#) and must satisfy the parallel resistance value requirement. The values in [Table 2-183](#) correspond to the resistor recommended when a single device is used and to the equivalent parallel resistor when multiple devices are connected via a JTAG chain.

In critical applications, an upset in the JTAG circuit could allow entering an undesired JTAG state. In such cases, Microsemi recommends tying off TRST to GND through a resistor placed close to the FPGA pin.

Note that to operate at all VJTAG voltages, 500 Ω to 1 k Ω will satisfy the requirements.

Special Function Pins

NC No Connect

This pin is not connected to circuitry within the device. These pins can be driven to any voltage or can be left floating with no effect on the operation of the device.

DC Don't Connect

This pin should not be connected to any signals on the PCB. These pins should be left unconnected.

NCAP Negative Capacitor

Negative Capacitor is where the negative terminal of the charge pump capacitor is connected. A capacitor, with a 2.2 μ F recommended value, is required to connect between PCAP and NCAP.

PCAP Positive Capacitor

Positive Capacitor is where the positive terminal of the charge pump capacitor is connected. A capacitor, with a 2.2 μ F recommended value, is required to connect between PCAP and NCAP.

PUB Push Button

Push button is the connection for the external momentary switch used to turn on the 1.5 V voltage regulator and can be floating if not used.

PTBASE Pass Transistor Base

Pass Transistor Base is the control signal of the voltage regulator. This pin should be connected to the base of the external pass transistor used with the 1.5 V internal voltage regulator and can be floating if not used.

PTEM Pass Transistor Emitter

Pass Transistor Emitter is the feedback input of the voltage regulator.

This pin should be connected to the emitter of the external pass transistor used with the 1.5 V internal voltage regulator and can be floating if not used.

XTAL1 Crystal Oscillator Circuit Input

Input to crystal oscillator circuit. Pin for connecting external crystal, ceramic resonator, RC network, or external clock input. When using an external crystal or ceramic oscillator, external capacitors are also recommended (Please refer to the crystal oscillator manufacturer for proper capacitor value).

If using external RC network or clock input, XTAL1 should be used and XTAL2 left unconnected. In the case where the Crystal Oscillator block is not used, the XTAL1 pin should be connected to GND and the XTAL2 pin should be left floating.

Total Static Power Consumption— P_{STAT}

Number of Quads used: $N_{QUADS} = 4$

Number of NVM blocks available (AFS600): $N_{NVM-BLOCKS} = 2$

Number of input pins used: $N_{INPUTS} = 30$

Number of output pins used: $N_{OUTPUTS} = 40$

Operating Mode

$$P_{STAT} = PDC1 + (N_{NVM-BLOCKS} * PDC4) + PDC5 + (N_{QUADS} * PDC6) + (N_{INPUTS} * PDC7) + (N_{OUTPUTS} * PDC8)$$

$$P_{STAT} = 7.50 \text{ mW} + (2 * 1.19 \text{ mW}) + 8.25 \text{ mW} + (4 * 3.30 \text{ mW}) + (30 * 0.00) + (40 * 0.00)$$

$$P_{STAT} = 31.33 \text{ mW}$$

Standby Mode

$$P_{STAT} = PDC2$$

$$P_{STAT} = 0.03 \text{ mW}$$

Sleep Mode

$$P_{STAT} = PDC3$$

$$P_{STAT} = 0.03 \text{ mW}$$

Total Power Consumption— P_{TOTAL}

In operating mode, the total power consumption of the device is 174.39 mW:

$$P_{TOTAL} = P_{STAT} + P_{DYN}$$

$$P_{TOTAL} = 143.06 \text{ mW} + 31.33 \text{ mW}$$

$$P_{TOTAL} = 174.39 \text{ mW}$$

In standby mode, the total power consumption of the device is limited to 0.66 mW:

$$P_{TOTAL} = P_{STAT} + P_{DYN}$$

$$P_{TOTAL} = 0.03 \text{ mW} + 0.63 \text{ mW}$$

$$P_{TOTAL} = 0.66 \text{ mW}$$

In sleep mode, the total power consumption of the device drops as low as 0.03 mW:

$$P_{TOTAL} = P_{STAT} + P_{DYN}$$

$$P_{TOTAL} = 0.03 \text{ mW}$$
