Welcome to [E-XFL.COM](#)**Understanding Embedded - FPGAs (Field Programmable Gate Array)**

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Architecture Overview

The MachXO family architecture contains an array of logic blocks surrounded by Programmable I/O (PIO). Some devices in this family have sysCLOCK PLLs and blocks of sysMEM™ Embedded Block RAM (EBRs). Figures 2-1, 2-2, and 2-3 show the block diagrams of the various family members.

The logic blocks are arranged in a two-dimensional grid with rows and columns. The EBR blocks are arranged in a column to the left of the logic array. The PIO cells are located at the periphery of the device, arranged into Banks. The PIOs utilize a flexible I/O buffer referred to as a sysIO interface that supports operation with a variety of interface standards. The blocks are connected with many vertical and horizontal routing channel resources. The place and route software tool automatically allocates these routing resources.

There are two kinds of logic blocks, the Programmable Functional Unit (PFU) and the Programmable Functional unit without RAM (PFF). The PFU contains the building blocks for logic, arithmetic, RAM, ROM, and register functions. The PFF block contains building blocks for logic, arithmetic, ROM, and register functions. Both the PFU and PFF blocks are optimized for flexibility, allowing complex designs to be implemented quickly and effectively. Logic blocks are arranged in a two-dimensional array. Only one type of block is used per row.

In the MachXO family, the number of sysIO Banks varies by device. There are different types of I/O Buffers on different Banks. See the details in later sections of this document. The sysMEM EBRs are large, dedicated fast memory blocks; these blocks are found only in the larger devices. These blocks can be configured as RAM, ROM or FIFO. FIFO support includes dedicated FIFO pointer and flag “hard” control logic to minimize LUT use.

The MachXO registers in PFU and sysI/O can be configured to be SET or RESET. After power up and device is configured, the device enters into user mode with these registers SET/RESET according to the configuration setting, allowing device entering to a known state for predictable system function.

The MachXO architecture provides up to two sysCLOCK™ Phase Locked Loop (PLL) blocks on larger devices. These blocks are located at either end of the memory blocks. The PLLs have multiply, divide, and phase shifting capabilities that are used to manage the frequency and phase relationships of the clocks.

Every device in the family has a JTAG Port that supports programming and configuration of the device as well as access to the user logic. The MachXO devices are available for operation from 3.3V, 2.5V, 1.8V, and 1.2V power supplies, providing easy integration into the overall system.

There are 14 input signals: 13 signals from routing and one from the carry-chain (from the adjacent Slice/PFU). There are 7 outputs: 6 to the routing and one to the carry-chain (to the adjacent Slice/PFU). Table 2-1 lists the signals associated with each Slice.

PFU Modes of Operation

Slices can be combined within a PFU to form larger functions. Table 2-4 tabulates these modes and documents the functionality possible at the PFU level.

Routing

There are many resources provided in the MachXO devices to route signals individually or as buses with related control signals. The routing resources consist of switching circuitry, buffers and metal interconnect (routing) segments.

The inter-PFU connections are made with three different types of routing resources: x1 (spans two PFUs), x2 (spans three PFUs) and x6 (spans seven PFUs). The x1, x2, and x6 connections provide fast and efficient connections in the horizontal and vertical directions.

of the devices also support differential input buffers. PCI clamps are available on the top Bank I/O buffers. The PCI clamp is enabled after V_{CC} , V_{CCAUX} , and V_{CCIO} are at valid operating levels and the device has been configured.

The two pads in the pair are described as “true” and “comp”, where the true pad is associated with the positive side of the differential input buffer and the comp (complementary) pad is associated with the negative side of the differential input buffer.

2. Left and Right sysIO Buffer Pairs

The sysIO buffer pairs in the left and right Banks of the device consist of two single-ended output drivers and two sets of single-ended input buffers (supporting ratioed and absolute input levels). The devices also have a differential driver per output pair. The referenced input buffer can also be configured as a differential input buffer. In these Banks the two pads in the pair are described as “true” and “comp”, where the true pad is associated with the positive side of the differential I/O, and the comp (complementary) pad is associated with the negative side of the differential I/O.

Typical I/O Behavior During Power-up

The internal power-on-reset (POR) signal is deactivated when V_{CC} and V_{CCAUX} have reached satisfactory levels. After the POR signal is deactivated, the FPGA core logic becomes active. It is the user's responsibility to ensure that all V_{CCIO} Banks are active with valid input logic levels to properly control the output logic states of all the I/O Banks that are critical to the application. The default configuration of the I/O pins in a blank device is tri-state with a weak pull-up to V_{CCIO} . The I/O pins will maintain the blank configuration until V_{CC} , V_{CCAUX} and V_{CCIO} have reached satisfactory levels at which time the I/Os will take on the user-configured settings.

The V_{CC} and V_{CCAUX} supply the power to the FPGA core fabric, whereas the V_{CCIO} supplies power to the I/O buffers. In order to simplify system design while providing consistent and predictable I/O behavior, the I/O buffers should be powered up along with the FPGA core fabric. Therefore, V_{CCIO} supplies should be powered up before or together with the V_{CC} and V_{CCAUX} supplies

Supported Standards

The MachXO sysIO buffer supports both single-ended and differential standards. Single-ended standards can be further subdivided into LVCMOS and LVTTL. The buffer supports the LVTTL, LVCMOS 1.2, 1.5, 1.8, 2.5, and 3.3V standards. In the LVCMOS and LVTTL modes, the buffer has individually configurable options for drive strength, bus maintenance (weak pull-up, weak pull-down, bus-keeper latch or none) and open drain. BLVDS and LVPECL output emulation is supported on all devices. The MachXO1200 and MachXO2280 support on-chip LVDS output buffers on approximately 50% of the I/Os on the left and right Banks. Differential receivers for LVDS, BLVDS and LVPECL are supported on all Banks of MachXO1200 and MachXO2280 devices. PCI support is provided in the top Banks of the MachXO1200 and MachXO2280 devices. Table 2-8 summarizes the I/O characteristics of the devices in the MachXO family.

Tables 2-9 and 2-10 show the I/O standards (together with their supply and reference voltages) supported by the MachXO devices. For further information on utilizing the sysIO buffer to support a variety of standards please see the details of additional technical documentation at the end of this data sheet.

sysIO Buffer Banks

The number of Banks vary between the devices of this family. Eight Banks surround the two larger devices, the MachXO1200 and MachXO2280 (two Banks per side). The MachXO640 has four Banks (one Bank per side). The smallest member of this family, the MachXO256, has only two Banks.

Each sysIO buffer Bank is capable of supporting multiple I/O standards. Each Bank has its own I/O supply voltage (V_{CCIO}) which allows it to be completely independent from the other Banks. Figure 2-18, Figure 2-18, Figure 2-20 and Figure 2-21 shows the sysIO Banks and their associated supplies for all devices.

1. Input or I/O leakage current is measured with the pin configured as an input or as an I/O with the output driver tri-stated. It is not measured with the output driver active. Bus maintenance circuits are disabled.

2. T_A 25°C, $f = 1.0MHz$

3. Please refer to V_{IL} and V_{IH} in the sysIO Single-Ended DC Electrical Characteristics table of this document.

4. Not applicable to SLEEPN pin.

5. When V_{IH} is higher than V_{CCIO} , a transient current typically of 30ns in duration or less with a peak current of 6mA can occur on the high-to-low transition. For MachXO1200 and MachXO2280 true LVDS output pins, V_{IH} must be less than or equal to V_{CCIO} .
