What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	dsPIC
Core Size	16-Bit
Speed	70 MIPs
Connectivity	I²C, IrDA, LINbus, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, POR, PWM, WDT
Number of I/O	21
Program Memory Size	64KB (64K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	8K x 8
Voltage - Supply (Vcc/Vdd)	3V ~ 3.6V
Data Converters	A/D 12x12b; D/A 1x12b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	28-VQFN Exposed Pad
Supplier Device Package	28-QFN-S (6x6)

8.1 CPU Clocking System

The dsPIC33EPXXGS50X family of devices provides six system clock options:

- Fast RC (FRC) Oscillator
- FRC Oscillator with Phase-Locked Loop (FRCPLL)
- FRC Oscillator with Postscaler
- Primary (XT, HS or EC) Oscillator
- Primary Oscillator with PLL
- Low-Power RC (LPRC) Oscillator

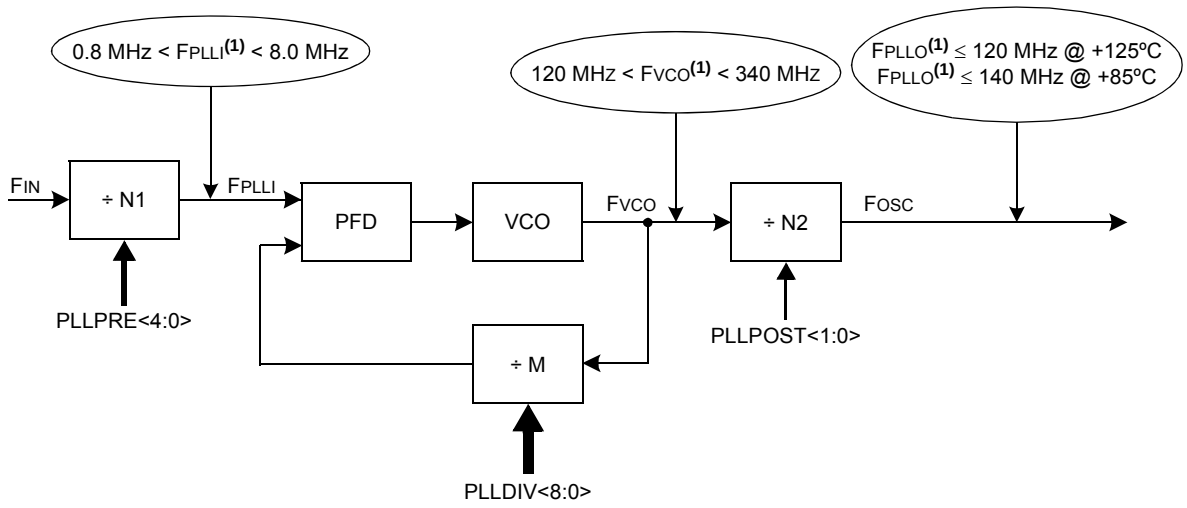
Instruction execution speed or device operating frequency, FCY, is given by Equation 8-1.

EQUATION 8-1: DEVICE OPERATING FREQUENCY

$$FCY = FOSC/2$$

Figure 8-2 is a block diagram of the PLL module. Equation 8-2 provides the relationship between Input Frequency (FIN) and Output Frequency (FPLLO). Equation 8-3 provides the relationship between Input Frequency (FIN) and VCO Frequency (FVCO).

FIGURE 8-2: PLL BLOCK DIAGRAM



Note 1: This frequency range must be met at all times.

EQUATION 8-2: FPLLO CALCULATION

$$FPLLO = FIN \times \left(\frac{M}{N1 \times N2}\right) = FIN \times \left(\frac{PLLDIV\langle 8:0\rangle + 2}{(PLLPRE\langle 4:0\rangle + 2) \times 2(PLLPOST\langle 1:0\rangle + 1)}\right)$$

Where:

$N1 = PLLPRE\langle 4:0\rangle + 2$

$N2 = 2 \text{ x } (PLLPOST\langle 1:0\rangle + 1)$

$M = PLLDIV\langle 8:0\rangle + 2$

EQUATION 8-3: FVCO CALCULATION

$$FVCO = FIN \times \left(\frac{M}{N1}\right) = FIN \times \left(\frac{PLLDIV\langle 8:0\rangle + 2}{(PLLPRE\langle 4:0\rangle + 2)}\right)$$

9.3 Doze Mode

The preferred strategies for reducing power consumption are changing clock speed and invoking one of the power-saving modes. In some circumstances, this cannot be practical. For example, it may be necessary for an application to maintain uninterrupted synchronous communication, even while it is doing nothing else. Reducing system clock speed can introduce communication errors, while using a power-saving mode can stop communications completely.

Doze mode is a simple and effective alternative method to reduce power consumption while the device is still executing code. In this mode, the system clock continues to operate from the same source and at the same speed. Peripheral modules continue to be clocked at the same speed, while the CPU clock speed is reduced. Synchronization between the two clock domains is maintained, allowing the peripherals to access the SFRs while the CPU executes code at a slower rate.

Doze mode is enabled by setting the DOZEN bit (CLKDIV<11>). The ratio between peripheral and core clock speed is determined by the DOZE<2:0> bits (CLKDIV<14:12>). There are eight possible configurations, from 1:1 to 1:128, with 1:1 being the default setting.

Programs can use Doze mode to selectively reduce power consumption in event-driven applications. This allows clock-sensitive functions, such as synchronous communications, to continue without interruption while the CPU Idles, waiting for something to invoke an interrupt routine. An automatic return to full-speed CPU operation on interrupts can be enabled by setting the ROI bit (CLKDIV<15>). By default, interrupt events have no effect on Doze mode operation.

9.4 Peripheral Module Disable

The Peripheral Module Disable (PMD) registers provide a method to disable a peripheral module by stopping all clock sources supplied to that module. When a peripheral is disabled using the appropriate PMD control bit, the peripheral is in a minimum power consumption state. The control and status registers associated with the peripheral are also disabled, so writes to those registers do not have any effect and read values are invalid.

A peripheral module is enabled only if both the associated bit in the PMD register is cleared and the peripheral is supported by the specific dsPIC® DSC variant. If the peripheral is present in the device, it is enabled in the PMD register by default.

Note:	If a PMD bit is set, the corresponding module is disabled after a delay of one instruction cycle. Similarly, if a PMD bit is cleared, the corresponding module is enabled after a delay of one instruction cycle (assuming the module control registers are already configured to enable module operation).

NOTES:

11.0 TIMER1

Note 1: This data sheet summarizes the features of the dsPIC33EPXXGS50X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to **"Timers"** (DS70362) in the *"dsPIC33/PIC24 Family Reference Manual"*, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to **Section 4.0 "Memory Organization"** in this data sheet for device-specific register and bit information.

The Timer1 module is a 16-bit timer that can operate as a free-running interval timer/counter.

The Timer1 module has the following unique features over other timers:

- Can be Operated in Asynchronous Counter mode from an External Clock Source
- The External Clock Input (T1CK) can Optionally be Synchronized to the Internal Device Clock and the Clock Synchronization is Performed after the Prescaler

A block diagram of Timer1 is shown in Figure 11-1.

The Timer1 module can operate in one of the following modes:

- Timer mode
- Gated Timer mode
- Synchronous Counter mode
- Asynchronous Counter mode

In Timer and Gated Timer modes, the input clock is derived from the internal instruction cycle clock (FCY). In Synchronous and Asynchronous Counter modes, the input clock is derived from the external clock input at the T1CK pin.

The Timer modes are determined by the following bits:

- Timer Clock Source Control bit (TCS): T1CON<1>
- Timer Synchronization Control bit (TSYNC): T1CON<2>
- Timer Gate Control bit (TGATE): T1CON<6>

Timer control bit settings for different operating modes are provided in Table 11-1.

17.0 INTER-INTEGRATED CIRCUIT (I^2C)

Note 1: This data sheet summarizes the features of the dsPIC33EPXXGS50X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to **"Inter-Integrated Circuit (I^2C)"** (DS70000195) in the *"dsPIC33/PIC24 Family Reference Manual"*, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to **Section 4.0 "Memory Organization"** in this data sheet for device-specific register and bit information.

The dsPIC33EPXXGS50X family of devices contains two Inter-Integrated Circuit (I^2C) modules: I2C1 and I2C2.

The I^2C module provides complete hardware support for both Slave and Multi-Master modes of the I^2C serial communication standard, with a 16-bit interface.

The I^2C module has a 2-pin interface:

- The SCLx/ASCLx pin is clock
- The SDAx/ASDAx pin is data

The I^2C module offers the following key features:

- I^2C Interface Supporting Both Master and Slave modes of Operation
- I^2C Slave mode Supports 7 and 10-Bit Addressing
- I^2C Master mode Supports 7 and 10-Bit Addressing
- I^2C Port allows Bidirectional Transfers between Master and Slaves
- Serial Clock Synchronization for I^2C Port can be used as a Handshake Mechanism to Suspend and Resume Serial Transfer (SCLREL control)
- I^2C Supports Multi-Master Operation, Detects Bus Collision and Arbitrates accordingly
- System Management Bus (SMBus) Support
- Alternate I^2C Pin Mapping (ASCLx/ASDAx)

22.0 CONSTANT-CURRENT SOURCE

Note 1: This data sheet summarizes the features of the dsPIC33EPXXGS50X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to the related section of the *"dsPIC33/PIC24 Family Reference Manual"*, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to **Section 4.0 "Memory Organization"** in this data sheet for device-specific register and bit information.

The constant-current source module is a precision current generator and is used in conjunction with the ADC module to measure the resistance of external resistors connected to device pins.

22.1 Features Overview

The constant-current source module offers the following major features:

- Constant-Current Generator (10 µA nominal)
- Internal Selectable Connection to One of Four Pins
- Enable/Disable Bit

22.2 Module Description

Figure 22-1 shows a functional block diagram of the constant-current source module. It consists of a precision current generator with a nominal value of 10 µA. The module can be enabled and disabled using the ISRCEN bit in the ISRCCON register. The output of the current generator is internally connected to a device pin. The dsPIC33EPXXGS50X family can have up to 4 selectable current source pins. The OUTSEL<2:0> bits in the ISRCCON register allow selection of the target pin.

The current source is calibrated during testing.

			—	6	—	mA/V	XT, VDD = 3.3V, TA = +25°C

Note 1: Data in “Typ.” column is at 3.3V, +25°C unless otherwise stated.

2: Instruction cycle period (TCY) equals two times the input oscillator time base period. All specified values are based on characterization data for that particular oscillator type, under standard operating conditions, with the device executing code. Exceeding these specified limits may result in an unstable oscillator operation and/or higher than expected current consumption. All devices are tested to operate at “Minimum” values with an external clock applied to the OSC1 pin. When an external clock input is used, the “Maximum” cycle time limit is “DC” (no clock) for all devices.

3: Measurements are taken in EC mode. The CLKO signal is measured on the OSC2 pin.

4: This parameter is characterized but not tested in manufacturing.
