

Welcome to [E-XFL.COM](https://www.e-xfl.com)

Understanding [Embedded - Microprocessors](#)

Embedded microprocessors are specialized computing chips designed to perform specific tasks within an embedded system. Unlike general-purpose microprocessors found in personal computers, embedded microprocessors are tailored for dedicated functions within larger systems, offering optimized performance, efficiency, and reliability. These microprocessors are integral to the operation of countless electronic devices, providing the computational power necessary for controlling processes, handling data, and managing communications.

Applications of [Embedded - Microprocessors](#)

Embedded microprocessors are utilized across a broad spectrum of applications, making them indispensable in

Details

Product Status	Active
Core Processor	Z80
Number of Cores/Bus Width	1 Core, 8-Bit
Speed	6MHz
Co-Processors/DSP	-
RAM Controllers	-
Graphics Acceleration	No
Display & Interface Controllers	-
Ethernet	-
SATA	-
USB	-
Voltage - I/O	5.0V
Operating Temperature	-40°C ~ 100°C (TA)
Security Features	-
Package / Case	44-LCC (J-Lead)
Supplier Device Package	44-PLCC
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z84c0006veg

GENERAL DESCRIPTION

The CPUs are fourth-generation enhanced microprocessors with exceptional computational power. They offer higher system throughput and more efficient memory utilization than comparable second- and third-generation microprocessors. The internal registers contain 208 bits of read/write memory that are accessible to the programmer. These registers include two sets of six general-purpose registers which may be used individually as either 8-bit registers or as 16-bit register pairs. In addition, there are two sets of accumulator and flag registers. A group of "Exchange" instructions makes either set of main or alternate registers accessible to the programmer. The alternate set allows operation in foreground-background mode or it may be reserved for very fast interrupt response.

The CPU also contains a Stack Pointer, Program Counter, two index registers, a Refresh register (counter), and an Interrupt register. The CPU is easy to incorporate into a system since it requires only a single +5V power source. All output signals are fully decoded and timed to control standard memory or peripheral circuits; the CPU is supported by an extensive family of peripheral controllers. The internal block diagram (Figure 3) shows the primary functions of the processors. Subsequent text provides more detail on the I/O controller family, registers, instruction set, interrupts and daisy chaining, and CPU timing.

SUMMARY OF FLAG OPERATION

Instructions	D ₇ S	Z	H	P/V	N	D ₀ C	Comments
ADD A, s; ADC A, s	†	†	X	†	X	V 0	8-bit add or add with carry.
SUB s; SBC A, s; CP s; NEG	†	†	X	†	X	V 1	8-bit subtract, subtract with carry, compare and negate accumulator.
AND s	†	†	X	1	X	P 0 0	Logical operation.
OR s, XOR s	†	†	X	0	X	P 0 0	Logical operation.
INC s	†	†	X	†	X	V 0 •	8-bit increment.
DEC s	†	†	X	†	X	V 1 •	8-bit decrement.
ADD DD, ss	•	•	X	X	X	• 0 †	16-bit add.
ADC HL, ss	†	†	X	X	X	V 0 †	16-bit add with carry.
SBC HL, ss	†	†	X	X	X	V 1 †	16-bit subtract with carry.
RLA; RLCA; RRA; RRCA	•	•	X	0	X	• 0 †	Rotate accumulator.
RL m; RLC m; RR m; RRC m; SLA m; SRA m; SRL m	†	†	X	0	X	P 0 †	Rotate and shift locations.
RLD; RRD	†	†	X	0	X	P 0 •	Rotate digit left and right.
DAA	†	†	X	†	X	P • †	Decimal adjust accumulator.
CPL	•	•	X	1	X	• 1 •	Complement accumulator.
SCF	•	•	X	0	X	• 0 1	Set carry.
CCF	•	•	X	X	X	• 0 †	Complement carry.
IN r (C)	†	†	X	0	X	P 0 •	Input register indirect.
INI; IND; OUTI; OUTD	X	†	X	X	X	X 1 •	Block input and output. Z = 1 if B ≠ 0, otherwise Z = 0.
INIR; INDR; OTIR; OTDR	X	1	X	X	X	X 1 •	Block input and output. Z = 1 if B ≠ 0, otherwise Z = 0.
LDI; LDD	X	X	X	0	X	† 0 •	Block transfer instructions. P/V = 1 if BC ≠ 0, otherwise P/V = 0.
LDIR; LDDR	X	X	X	0	X	0 0 •	Block transfer instructions. P/V = 1 if BC ≠ 0, otherwise P/V = 0.
CPI; CPIR; CPD; CPDR	X	†	X	X	X	† 1 •	Block search instructions. Z = 1 if A = (HL), otherwise Z = 0. P/V = 1 if BC ≠ 0, otherwise P/V = 0.
LD A, I; LD A, R	†	†	X	0	X	IFF 0 •	IFF, the content of the interrupt enable flip-flop, (IFF ₂), is copied into the P/V flag.
BIT b, s	X	†	X	1	X	X 0 •	The state of bit b of location s is copied into the Z flag.

SYMBOLIC NOTATION

Symbol	Operation	Symbol	Operation
S	Sign flag. S = 1 if the MSB of the result is 1.	†	The flag is affected according to the result of the operation.
Z	Zero flag. Z = 1 if the result of the operation is 0.	•	The flag is unchanged by the operation.
P/V	Parity or overflow flag. Parity (P) and overflow (V) share the same flag. Logical operations affect this flag with the parity of the result while arithmetic operations affect this flag with the overflow of the result. If P/V holds parity: P/V = 1 if the result of the operation is even; P/V = 0 if result is odd. If P/V holds overflow, P/V = 1 if the result of the operation produced an overflow. If P/V does not hold overflow, P/V = 0.	0	The flag is reset by the operation.
H*	Half-carry flag. H = 1 if the add or subtract operation produced a carry into, or borrow from, bit 4 of the accumulator.	1	The flag is set by the operation.
N*	Add/Subtract flag. N = 1 if the previous operation was a subtract.	X	The flag is indeterminate.
C	Carry/Link flag. C = 1 if the operation produced a carry from the MSB of the operand or result.	V	P/V flag affected according to the overflow result of the operation.
		P	P/V flag affected according to the parity result of the operation.
		r	Any one of the CPU registers A, B, C, D, E, H, L.
		s	Any 8-bit location for all the addressing modes allowed for the particular instruction.
		ss	Any 16-bit location for all the addressing modes allowed for that instruction.
		ii	Any one of the two index registers IX or IY.
		R	Refresh counter.
		n	8-bit value in range < 0, 255 >.
		nn	16-bit value in range < 0, 65535 >.

* H and N flags are used in conjunction with the decimal adjust instruction (DAA) to properly correct the result into packed BCD format following addition or subtraction using operands with packed BCD format.

CPU REGISTERS

Figure 4 shows three groups of registers within the CPU. The first group consists of duplicate sets of 8-bit registers: a principal set and an alternate set [designated by ' (prime), e.g., A']. Both sets consist of the Accumulator register, the Flag register, and six general-purpose registers. Transfer of data between these duplicate sets of registers is accomplished by use of "Exchange" instructions. The result is faster response to interrupts and easy, efficient implementation of such versatile programming techniques

as background-foreground data processing. The second set of registers consists of six registers with assigned functions. These are the I (Interrupt register), the R (Refresh register), the IX and IY (Index registers), the SP (Stack Pointer), and the PC (Program Counter). The third group consists of two interrupt status flip-flops, plus an additional pair of flip-flops which assists in identifying the interrupt mode at any particular time. Table 1 provides further information on these registers.

Figure 4. CPU Registers

INTERRUPTS: GENERAL OPERATION

The CPU accepts two interrupt input signals: $\overline{\text{NMI}}$ and $\overline{\text{INT}}$. The $\overline{\text{NMI}}$ is a non-maskable interrupt and has the highest priority. $\overline{\text{INT}}$ is a lower priority interrupt and it requires that interrupts be enabled in software in order to operate. $\overline{\text{INT}}$ can be connected to multiple peripheral devices in a wired-OR configuration.

The Z80 has a single response mode for interrupt service on the non-maskable interrupt. The maskable interrupt, $\overline{\text{INT}}$, has three programmable response modes available. These are:

- Mode 0 — similar to the 8080 microprocessor.
- Mode 1 — Peripheral Interrupt service, for use with non-8080/Z80 systems.

- Mode 2 - a vectored interrupt scheme, usually daisy-chained, for use with the Z80 Family and compatible peripheral devices.

The CPU services interrupts by sampling the $\overline{\text{NMI}}$ and $\overline{\text{INT}}$ signals at the rising edge of the last clock of an instruction. Further interrupt service processing depends upon the type of interrupt that was detected. Details on interrupt responses are shown in the CPU Timing Section.

Non-Maskable Interrupt ($\overline{\text{NMI}}$). The nonmaskable interrupt cannot be disabled by program control and therefore will be accepted at all times by the CPU. $\overline{\text{NMI}}$ is usually reserved for servicing only the highest priority type interrupts, such as that for orderly shutdown after power

PIN DESCRIPTIONS

A₀-A₁₅. *Address Bus* (output, active High, 3-state). A₀-A₁₅ form a 16-bit address bus. The Address Bus provides the address for memory data bus exchanges (up to 64K bytes) and for I/O device exchanges.

BUSACK. *Bus Acknowledge* (output, active Low). Bus Acknowledge indicates to the requesting device that the CPU address bus, data bus, and control signals $\overline{\text{MREQ}}$, $\overline{\text{IORQ}}$, $\overline{\text{RD}}$, and $\overline{\text{WR}}$ have entered their high-impedance states. The external circuitry can now control these lines.

BUSREQ. *Bus Request* (input, active Low). Bus Request has a higher priority than $\overline{\text{NMI}}$ and is always recognized at the end of the current machine cycle. $\overline{\text{BUSREQ}}$ forces the CPU address bus, data bus, and control signals $\overline{\text{MREQ}}$, $\overline{\text{IORQ}}$, $\overline{\text{RD}}$, and $\overline{\text{WR}}$ to go to a high-impedance state so that other devices can control these lines. $\overline{\text{BUSREQ}}$ is normally wired-OR and requires an external pullup for these applications. Extended $\overline{\text{BUSREQ}}$ periods due to extensive DMA operations can prevent the CPU from properly refreshing dynamic RAMs.

D₀-D₇. *Data Bus* (input/output, active High, 3-state). D₀-D₇ constitute an 8-bit bidirectional data bus, used for data exchanges with memory and I/O.

HALT. *Halt State* (output, active Low). $\overline{\text{HALT}}$ indicates that the CPU has executed a Halt instruction and is awaiting either a nonmaskable or a maskable interrupt (with the mask enabled) before operation can resume. While halted, the CPU executes NOPs to maintain memory refresh.

INT. *Interrupt Request* (input, active Low). Interrupt Request is generated by I/O devices. The CPU honors a request at the end of the current instruction if the internal software-controlled interrupt enable flip-flop (IFF) is enabled. $\overline{\text{INT}}$ is normally wired-OR and requires an external pullup for these applications.

IORQ. *Input/Output Request* (output, active Low, 3-state). $\overline{\text{IORQ}}$ indicates that the lower half of the address bus holds a valid I/O address for an I/O read or write operation. $\overline{\text{IORQ}}$ is also generated concurrently with $\overline{\text{M1}}$ during an interrupt acknowledge cycle to indicate that an interrupt response vector can be placed on the data bus.

M1. *Machine Cycle One* (output, active Low). $\overline{\text{M1}}$, together with $\overline{\text{MREQ}}$, indicates that the current machine cycle is the opcode fetch cycle of an instruction execution. $\overline{\text{M1}}$, together with $\overline{\text{IORQ}}$, indicates an interrupt acknowledge cycle.

MREQ. *Memory Request* (output, active Low, 3-state). $\overline{\text{MREQ}}$ indicates that the address bus holds a valid address for a memory read or memory write operation.

NMI. *Non-Maskable Interrupt* (input, negative edge-triggered). $\overline{\text{NMI}}$ has a higher priority than $\overline{\text{INT}}$. $\overline{\text{NMI}}$ is always recognized at the end of the current instruction, independent of the status of the interrupt enable flip-flop, and automatically forces the CPU to restart at location 0066H.

RD. *Read* (output, active Low, 3-state). $\overline{\text{RD}}$ indicates that the CPU wants to read data from memory or an I/O device. The addressed I/O device or memory should use this signal to gate data onto the CPU data bus.

RESET. *Reset* (input, active Low). $\overline{\text{RESET}}$ initializes the CPU as follows: it resets the interrupt enable flip-flop, clears the PC and Registers I and R, and sets the interrupt status to Mode 0. During reset time, the address and data bus go to a high-impedance state, and all control output signals go to the inactive state. Note that $\overline{\text{RESET}}$ must be active for a minimum of three full clock cycles before the reset operation is complete.

RFSH. *Refresh* (output, active Low). $\overline{\text{RFSH}}$, together with $\overline{\text{MREQ}}$, indicates that the lower seven bits of the system's address bus can be used as a refresh address to the system's dynamic memories.

WAIT. *Wait* (input, active Low). $\overline{\text{WAIT}}$ indicates to the CPU that the addressed memory or I/O devices are not ready for a data transfer. The CPU continues to enter a Wait state as long as this signal is active. Extended $\overline{\text{WAIT}}$ periods can prevent the CPU from properly refreshing dynamic memory.

WR. *Write* (output, active Low, 3-state). $\overline{\text{WR}}$ indicates that the CPU data bus holds valid data to be stored at the addressed memory or I/O location.

CPU TIMING

The Z80 CPU executes instructions by proceeding through a specific sequence of operations:

- Memory read or write
- I/O device read or write
- Interrupt acknowledge

The basic clock period is referred to as a T time or cycle, and three or more T cycles make up a machine cycle (M1, M2 or M3 for instance). Machine cycles can be extended either by the CPU automatically inserting one or more Wait states or by the insertion of one or more Wait states by the user.

Instruction Opcode Fetch. The CPU places the contents of the Program Counter (PC) on the address bus at the start of the cycle (Figure 5). Approximately one-half clock cycle later, $\overline{\text{MREQ}}$ goes active. When active, $\overline{\text{RD}}$ indicates that the memory data can be enabled onto the CPU data bus.

The CPU samples the $\overline{\text{WAIT}}$ input with the falling edge of clock state T₂. During clock states T₃ and T₄ of an M1 cycle, dynamic RAM refresh can occur while the CPU starts decoding and executing the instruction. When the Refresh Control signal becomes active, refreshing of dynamic memory can take place.

Figure 5. Instruction Opcode Fetch

Memory Read or Write Cycles. Figure 6 shows the timing of memory read or write cycles other than an opcode fetch (M1) cycle. The \overline{MREQ} and \overline{RD} signals function exactly as in the fetch cycle. In a memory write cycle, \overline{MREQ} also

becomes active when the address bus is stable. The \overline{WR} line is active when the data bus is stable, so that it can be used directly as an R/W pulse to most semiconductor memories.

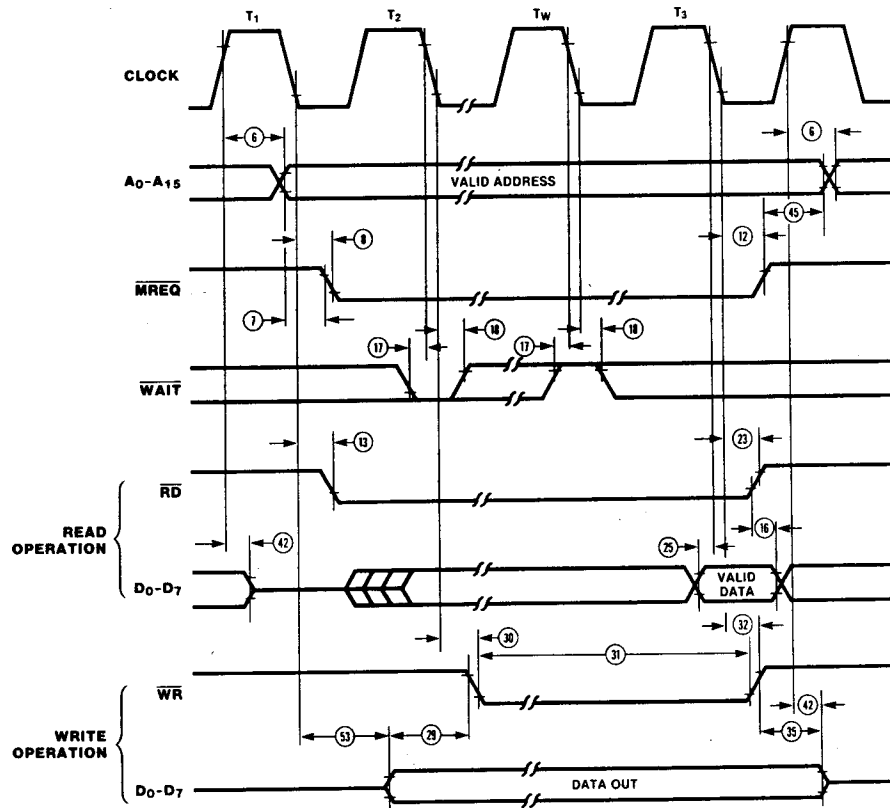

Figure 6. Memory Read or Write Cycles

Input or Output Cycles. Figure 7 shows the timing for an I/O read or I/O write operation. During I/O operations, the CPU automatically inserts a single Wait state (T_{WA}). This

extra Wait state allows sufficient time for an I/O port to decode the address from the port address lines.

T_{WA} = One wait cycle automatically inserted by CPU.

Figure 7. Input or Output Cycles

Non-Maskable Interrupt Request Cycle. $\overline{\text{NMI}}$ is sampled at the same time as the maskable interrupt input $\overline{\text{INT}}$ but has higher priority and cannot be disabled under software control. The subsequent timing is similar to that of a normal

memory read operation except that data put on the bus by the memory is ignored. The CPU instead executes a restart (RST) operation and jumps to the $\overline{\text{NMI}}$ service routine located at address 0066H (Figure 9).

*Although $\overline{\text{NMI}}$ is an asynchronous input, to guarantee its being recognized on the following machine cycle, $\overline{\text{NMI}}$'s falling edge must occur no later than the rising edge of the clock cycle preceding the last state of any instruction cycle (T_{L1}).

Figure 9. Non-Maskable Interrupt Request Operation

Halt Acknowledge Cycle. When the CPU receives a $\overline{\text{HALT}}$ instruction, it executes NOP states until either an $\overline{\text{INT}}$ or $\overline{\text{NMI}}$ input is received. When in the Halt state, the $\overline{\text{HALT}}$ output is

active and remains so until an interrupt is received (Figure 11). $\overline{\text{INT}}$ will also force a Halt exit.

*Although $\overline{\text{NMI}}$ is an asynchronous input, to guarantee its being recognized on the following machine cycle, $\overline{\text{NMI}}$'s falling edge must occur no later than the rising edge of the clock cycle preceding the last state of any instruction cycle (T_{LJ}).

Figure 11. Halt Acknowledge

Reset Cycle. $\overline{\text{RESET}}$ must be active for at least three clock cycles for the CPU to properly accept it. As long as $\overline{\text{RESET}}$ remains active, the address and data buses float, and the control outputs are inactive. Once $\overline{\text{RESET}}$ goes inactive, two

internal T cycles are consumed before the CPU resumes normal processing operation. $\overline{\text{RESET}}$ clears the PC register, so the first opcode fetch will be to location 0000H (Figure 12).

Figure 12. Reset Cycle

Power-Down mode of operation (Only applies to CMOS Z80 CPU).

CMOS Z80 CPU supports Power-Down mode of operation.

This mode is also referred to as the "standby mode", and supply current for the CPU goes down as low as 10 μA (Where specified as I_{CC2}).

Power-Down Acknowledge Cycle. When the clock input to the CPU is stopped at either a High or Low level, the CPU stops its operation and maintains all registers and control signals. However, I_{CC2} (standby supply current) is guaranteed only when the system clock is stopped at a Low

level during T_4 of the machine cycle following the execution of the HALT instruction. The timing diagram for the power-down function, when implemented with the HALT instruction, is shown in Figure 13.

Figure 13. Power-Down Acknowledge

DC CHARACTERISTICS (Z84C00/CMOS Z80 CPU)

Symbol	Parameter	Min	Max	Unit	Condition
V_{ILC}	Clock Input Low Voltage	-0.3	0.45	V	
V_{IHC}	Clock Input High Voltage	$V_{CC} - .6$	$V_{CC} + .3$	V	
V_{IL}	Input Low Voltage	-0.3	0.8	V	
V_{IH}	Input High Voltage	2.2	V_{CC}	V	
V_{OL}	Output Low Voltage		0.4	V	$I_{OL} = 2.0 \text{ mA}$
V_{OH1}	Output High Voltage	2.4		V	$I_{OH} = -1.6 \text{ mA}$
V_{OH2}	Output High Voltage	$V_{CC} - 0.8$		V	$I_{OH} = -250 \mu\text{A}$
I_{CC1}	Power Supply Current	4 MHz	20	mA	$V_{CC} = 5\text{V}$
			30	mA	$V_{IH} = V_{CC} - 0.2\text{V}$
			40	mA	$V_{IL} = 0.2\text{V}$
			50	mA	$V_{CC} = 5\text{V}$
			100	mA	$V_{CC} = 5\text{V}$
I_{CC2}	Standby Supply Current		10	μA	$V_{CC} = 5\text{V}$ CLK = (0) $V_{IH} = V_{CC} - 0.2\text{V}$ $V_{IL} = 0.2\text{V}$
I_{LI}	Input Leakage Current	-10	10	μA	$V_{IN} = 0.4 \text{ to } V_{CC}$
I_{LO}	3-State Output Leakage Current in Float	-10	10^2	μA	$V_{OUT} = 0.4 \text{ to } V_{CC}$

1. Measurements made with outputs floating.

2. A₁₅-A₀, D₇-D₀, MREQ, IORQ, RD, and WR.

3. I_{CC2} standby supply current is guaranteed only when the supplied clock is stopped at a low level during T₄ of the machine cycle immediately following the execution of a HALT instruction.

CAPACITANCE

Symbol	Parameter	Min	Max	Unit
C_{CLOCK}	Clock Capacitance		10	pf
C_{IN}	Input Capacitance		5	pf
C_{OUT}	Output Capacitance		15	pf

T_A = 25°C, f = 1 MHz.

Unmeasured pins returned to ground.

Notes:

* For Clock periods other than the minimum shown, calculate parameters using the following table.

Calculated values above assumed TrC = TrC = maximum.

** 4 MHz CMOS Z80 is obsoleted and replaced by 6 MHz

[1] Z84C0020 parameters are guaranteed with 50pF load Capacitance.

[2] If Capacitive Load is other than 50pF, please use Figure 1. to calculate the value.

[3] Increasing delay by 10nS for each 50pF increase in loading, 200pF max for data lines, and 100pF for control lines.
