Welcome to E-XFL.COM

#### What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "<u>Embedded -</u> <u>Microcontrollers</u>"

#### Details

| Product Status             | Active  |
|----------------------------|---|
| Core Processor             | eZ8   |
| Core Size                  | 8-Bit   |
| Speed                      | 20MHz   |
| Connectivity               | -   |
| Peripherals                | Brown-out Detect/Reset, LED, POR, PWM, WDT                |
| Number of I/O              | 17  |
| Program Memory Size        | 1KB (1K x 8)  |
| Program Memory Type        | FLASH   |
| EEPROM Size                | -   |
| RAM Size                   | 256 x 8   |
| Voltage - Supply (Vcc/Vdd) | 2.7V ~ 3.6V   |
| Data Converters            | A/D 7x10b   |
| Oscillator Type            | Internal  |
| Operating Temperature      | -40°C ~ 105°C (TA)  |
| Mounting Type              | Surface Mount   |
| Package / Case             | 20-VQFN Exposed Pad                                       |
| Supplier Device Package    | -   |

# **Address Space**

The eZ8 CPU can access the following three distinct address spaces:

- The register file addresses access for the general purpose registers and the eZ8 CPU, peripheral and general purpose I/O port control registers
- The program memory addresses access for all of the memory locations having executable code and/or data
- The data memory addresses access for all of the memory locations containing only the data

The following sections describe these three address spaces. For more information about the eZ8 CPU and its address space, refer to the <u>eZ8 CPU Core User Manual (UM0128)</u>, which is available for download at <u>www.zilog.com</u>.

# **Register File**

The register file address space in the Z8 Encore! MCU is 4KB (4096 bytes). The register file consists of two sections: control registers and general-purpose registers. When instructions are executed, registers defined as *source* are read and registers defined as *destinations* are written. The architecture of the eZ8 CPU allows all general purpose registers to function as accumulators, address pointers, index registers, stack areas or scratch pad memory.

The upper 256 bytes of the 4KB register file address space are reserved for controlling the eZ8 CPU, on-chip peripherals and the I/O ports. These registers are located at addresses from F00H to FFFH. Some of the addresses within the 256B Control Register section are reserved (unavailable). Reading from a reserved register file address returns an undefined value. Writing to reserved register file addresses is not recommended and can produce unpredictable results.

The on-chip RAM always begins at address 000H in the register file address space. The Z8 Encore! F0830 Series devices contain up to 256B of on-chip RAM. Reading from register file addresses outside the available RAM addresses (and not within the Control Register address space), returns an undefined value. Writing to these register file addresses has no effect.

## Z8 Encore!<sup>®</sup> F0830 Series Product Specification

# Architecture

Figure 9 displays the Interrupt Controller block diagram.

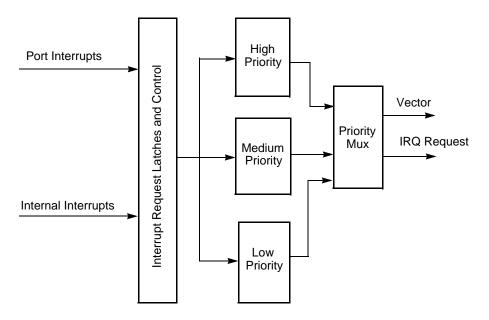

Figure 9. Interrupt Controller Block Diagram

# Operation

This section describes the operational aspects of the following functions.

Master Interrupt Enable: see page 55

Interrupt Vectors and Priority: see page 56

Interrupt Assertion: see page 56

Software Interrupt Assertion: see page 57

# **Master Interrupt Enable**

The master interrupt enable bit (IRQE) in the Interrupt Control Register globally enables and disables the interrupts.

Interrupts are globally enabled by any of the following actions:

- Execution of an EI (enable interrupt) instruction
- Execution of an IRET (return from interrupt) instruction

## 73

# **Caution:** The frequency of the comparator output signal must not exceed one-fourth the system clock frequency.

After reaching the reload value stored in the Timer Reload High and Low Byte registers, the timer generates an interrupt, the count value in the Timer High and Low Byte registers is reset to 0001H and counting resumes. Additionally, if the timer output alternate function is enabled, the timer output pin changes state (from Low to High or from High to Low) at timer reload.

Observe the following steps for configuring a timer for COMPARATOR COUNTER Mode and for initiating the count:

- 1. Write to the Timer Control Register to:
  - Disable the timer
  - Configure the timer for COMPARATOR COUNTER Mode.
  - Select either the rising edge or falling edge of the comparator output signal for the count. This also sets the initial logic level (High or Low) for the timer output alternate function. However, the timer output function is not required to be enabled.
- 2. Write to the Timer High and Low Byte registers to set the starting count value. This action only affects the first pass in COMPARATOR COUNTER Mode. After the first timer reload in COMPARATOR COUNTER Mode, counting always begins at the reset value 0001H. Generally, in COMPARATOR COUNTER Mode, the Timer High and Low Byte registers must be written with the value 0001H.
- 3. Write to the Timer Reload High and Low Byte registers to set the reload value.
- 4. If appropriate, enable the timer interrupt and set the timer interrupt priority by writing to the relevant interrupt registers.
- 5. If using the timer output function, configure the associated GPIO port pin for the timer output alternate function.
- 6. Write to the Timer Control Register to enable the timer.

In COMPARATOR COUNTER Mode, the number of comparator output transitions is calculated with the following equation:

Comparator Output Transitions = Current Count Value – Start Value

- 5. Enable the timer interrupt, if appropriate and set the timer interrupt priority by writing to the relevant interrupt registers. By default, the timer interrupt is generated for both input capture and Reload events. If appropriate, configure the timer interrupt to be generated only at the input capture event or the reload event by setting the TICONFIG field of the TxCTL1 Register.
- 6. Configure the associated GPIO port pin for the timer input alternate function.
- 7. Write to the Timer Control Register to enable the timer and initiate counting.

In CAPTURE Mode, the elapsed time between the timer start and the capture event can be calculated using the following equation:

Capture Elapsed Time (s) =  $\frac{(Capture Value - Start Value) \times Prescale}{System Clock Frequency (Hz)}$ 

## **CAPTURE RESTART Mode**

In CAPTURE RESTART Mode, the current timer count value is recorded when the acceptable external timer input transition occurs. The capture count value is written to the timer PWM High and Low Byte registers. The timer input is the system clock. The TPOL bit in the Timer Control Register determines whether the capture occurs on a rising edge or a falling edge of the timer input signal. When the capture event occurs, an interrupt is generated and the count value in the Timer High and Low Byte registers is reset to 0001H and counting resumes. The INPCAP bit in the TxCTL1 Register is set to indicate that the timer interrupt has been caused by an input capture event.

If no capture event occurs, the timer counts up to 16-bit compare value stored in the Timer Reload High and Low Byte registers. Upon reaching the reload value, the timer generates an interrupt, the count value in the Timer High and Low Byte registers is reset to 0001H and counting resumes. The INPCAP bit in the TxCTL1 Register is cleared to indicate that the timer interrupt has not been caused by an input capture event.

Observe the following steps for configuring a timer for CAPTURE RESTART Mode and for initiating the count:

- 1. Write to the Timer Control Register to:
  - Disable the timer
  - Configure the timer for CAPTURE RESTART Mode; setting the mode also involves writing to TMODEHI bit in the TxCTL1 Register
  - Set the prescale value
  - Set the capture edge (rising or falling) for the timer input
- 2. Write to the Timer High and Low Byte registers to set the starting count value (typically 0001H).

## Watchdog Timer Refresh

Upon first enable, the Watchdog Timer is loaded with the value in the Watchdog Timer Reload registers. The Watchdog Timer counts down to 000000H unless a WDT instruction is executed by the eZ8 CPU. Execution of the WDT instruction causes the downcounter to be reloaded with the WDT reload value stored in the Watchdog Timer Reload registers. Counting resumes following the Reload operation.

When the Z8 Encore! F0830 Series devices are operating in DEBUG Mode (using the On-Chip Debugger), the Watchdog Timer must be continuously refreshed to prevent any WDT time-outs.

## Watchdog Timer Time-Out Response

The Watchdog Timer times out when the counter reaches 000000H. A time-out of the Watchdog Timer generates either an interrupt or a system reset. The WDT\_RES Flash option bit determines the time-out response of the Watchdog Timer. See *the* <u>Flash Option</u> <u>Bits</u> chapter on page 124 for information about programming the WDT\_RES Flash option bit.

## **WDT Interrupt in Normal Operation**

If configured to generate an interrupt when a time-out occurs, the Watchdog Timer issues an interrupt request to the Interrupt Controller and sets the WDT status bit in the Reset Status Register. If interrupts are enabled, the eZ8 CPU responds to the interrupt request by fetching the Watchdog Timer interrupt vector and executing code from the vector address. After time-out and interrupt generation, the Watchdog Timer counter resets to its maximum value of FFFFFH and continues counting. The Watchdog Timer counter will not automatically return to its reload value.

The Reset Status Register (see <u>Table 12</u> on page 29) must be read before clearing the WDT interrupt. This read clears the WDT time-out flag and prevents further WDT interrupts occurring immediately.

## WDT Interrupt in STOP Mode

If configured to generate an interrupt when a time-out occurs and the Z8 Encore! F0830 Series devices are in STOP Mode, the Watchdog Timer automatically initiates a Stop Mode Recovery and generates an interrupt request. Both the WDT status bit and the STOP bit in the Watchdog Timer Control Register are set to 1 following a WDT time-out in STOP Mode. See *the* <u>Reset and Stop Mode Recovery</u> *chapter on page 21* for more information about Stop Mode Recovery operations.

If interrupts are enabled, following completion of the Stop Mode Recovery, the eZ8 CPU responds to the interrupt request by fetching the Watchdog Timer interrupt vector and executes the code from the vector address.

## ADC Data High Byte Register

The ADC Data High Byte Register, listed in Table 64, contains the upper eight bits of the ADC output. Access to the ADC Data High Byte Register is read-only. Reading the ADC Data High Byte Register latches data in the ADC Low Bits Register.

### Table 64. ADC Data High Byte Register (ADCD\_H)

| Bit     | 7     | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---------|-------|---|---|---|---|---|---|---|
| Field   | ADCDH |   |   |   |   |   |   |   |
| RESET   |       | Х |   |   |   |   |   |   |
| R/W     | R     |   |   |   |   |   |   |   |
| Address | F72H  |   |   |   |   |   |   |   |
|         |       |   |   |   |   |   |   |   |

| Bit   | Description   |
|-------|---|
| [7:0] | ADC High Byte   |
| ADCDH | 00h–FFh = The last conversion output is held in the data registers until the next ADC conver-<br>sion is completed. |

## ADC Data Low Bits Register

The ADC Data Low Bits Register, shown in Table 65, contains the lower bits of the ADC output. Access to the ADC Data Low Bits Register is read-only. Reading the ADC Data High Byte Register latches lower bits of the ADC in the ADC Data Low Bits Register.

| Bit     | 7     | 6 | 5        | 4 | 3 | 2 | 1 | 0 |
|---------|-------|---|----------|---|---|---|---|---|
| Field   | ADCDL |   | Reserved |   |   |   |   |   |
| RESET   | Х     |   | X        |   |   |   |   |   |
| R/W     | F     | २ |          | R |   |   |   |   |
| Address | F73H  |   |          |   |   |   |   |   |

| Table 65. | ADC Data L | ow Bits R | Register (A | ADCD_L) |
|-----------|------------|-----------|-------------|---------|
|-----------|------------|-----------|-------------|---------|

| Bit            | Description  |
|----------------|--|
| [7:6]<br>ADCDL | ADC Low Bits<br>00–11b = These bits are the two least-significant bits of the 10-bit ADC output. These bits are<br>undefined after a reset. The low bits are latched into this register whenever the ADC Data High<br>Byte Register is read. |
| [5:0]          | <b>Reserved</b><br>These bits are reserved and must be programmed to 000000.   |

## Sample Settling Time Register

The <u>Sample Settling</u> Time Register, shown in Table 66, is used to program a delay after the <u>SAMPLE/HOLD</u> signal is asserted and before the START signal is asserted; an ADC conversion then begins. The number of clock cycles required for settling will vary from system to system depending on the system clock period used. The system designer should program this register to contain the number of clocks required to meet a  $0.5 \mu s$  minimum settling time.

| Bit     | 7    | 6    | 5     | 4 | 3 | 2  | 1  | 0 |
|---------|------|------|-------|---|---|----|----|---|
| Field   |      | Rese | erved |   |   | S  | ST |   |
| RESET   | 0    |      |       |   | 1 | 1  | 1  | 1 |
| R/W     |      | F    | २     |   |   | R/ | W  |   |
| Address | F74H |      |       |   |   |    |    |   |

## Table 66. Sample Settling Time (ADCSST)

| Bit          | Description   |
|--------------|---|
| [7:4]        | <b>Reserved</b><br>These bits are reserved and must be programmed to 0000.                  |
| [3:0]<br>SST | 0h–Fh = Sample settling time in number of system clock periods to meet 0.5 $\mu$ s minimum. |

# Flash Memory

The products in the Z8 Encore! F0830 Series features either 1KB (1024 bytes with NVDS), 2KB (2048 bytes with NVDS), 4KB (4096 bytes with NVDS), 8KB (8192 bytes with NVDS) or 12KB (12288 bytes with no NVDS) of nonvolatile Flash memory with read/write/erase capability. Flash memory can be programmed and erased in-circuit by either user code or through the On-Chip Debugger.

The Flash memory array is arranged in pages with 512 bytes per page. The 512-byte page is the minimum Flash block size that can be erased. Each page is divided into eight rows of 64 bytes.

For program/data protection, Flash memory is also divided into sectors. In the Z8 Encore! F0830 Series, each sector maps to one page (for 1KB, 2KB and 4KB devices), two pages (8KB device) or three pages (12KB device).

The first two bytes of Flash program memory is used as Flash option bits. For more information, see *the* <u>Flash Option Bits</u> chapter on page 124.

Table 69 lists the Flash memory configuration for each device in the Z8 Encore! F0830 Series. Figures 14 through 18 display the memory arrangements for each Flash memory size.

| Part Number | Flash Size<br>KB (Bytes) | Flash Pages | Program<br>Memory<br>Addresses | Flash Sector<br>Size (bytes) |
|-------------|--------------------------|-------------|--------------------------------|------------------------------|
| Z8F123x     | 12 (12,288)              | 24          | 0000H–2FFFH                    | 1536                         |
| Z8F083x     | 8 (8196)                 | 16          | 0000H-1FFFH                    | 1024                         |
| Z8F043x     | 4 (4096)                 | 8           | 0000H–0FFFH                    | 512                          |
| Z8F023x     | 2 (2048)                 | 4           | 0000H–07FFH                    | 512                          |
| Z8F013x     | 1 (1024)                 | 2           | 0000H-03FFH                    | 512                          |

| FHSWP  | FWP | Flash Code Protection Description  |
|--------|-----|--|
| 0      | 0   | Programming and erasing disabled for all Flash program memory. In user code pro-<br>gramming, page erase and mass erase are all disabled. Mass erase is available<br>through the On-Chip Debugger. |
| 0 or 1 | 1   | Programming, page erase and mass erase are enabled for all of the Flash program memory.  |

#### Table 71. Flash Code Protection using the Flash Option Bits

At reset, the Flash Controller is locked to prevent accidental program or erasure of Flash memory. To program or erase Flash memory, first write the target page to the page select register. Unlock the Flash Controller by making two consecutive writes to the Flash Control Register with the values 73H and 8CH, sequentially. The page select register must be rewritten with the same page previously stored there. If the two page select writes do not match, the controller reverts to a Locked state. If the two writes match, the selected page becomes active. See Figure 19 for details.

After unlocking a specific page, you can enable either page program or erase. Writing the value 95H causes a page erase only if the active page resides in a sector that is not protected. Any other value written to the Flash Control Register locks the Flash Controller. Mass erase is not allowed in the user code, but is allowed through the debug port.

After unlocking a specific page, the user can also write to any byte on that page. After a byte is written, the page remains unlocked, allowing for subsequent writes to other bytes on the same page. Further writes to the Flash Control Register causes the active page to revert to a Locked state.

#### **Sector Based Flash Protection**

The final protection mechanism is implemented on a per-sector basis. The Flash memories of Z8 Encore! devices are divided into maximum number of eight sectors. A sector is oneeighth of the total size of Flash memory, unless this value is smaller than the page size, in which case the sector and page sizes are equal. On Z8 Encore! F0830 Series devices, the sector size is varied according to the Z8 Encore! F0830 Series Flash Memory Configuration shown in Table 69 on page 108 and in Figures 14 through 18, which follow the table

The Flash Sector Protect Register can be configured to prevent sectors from being programmed or erased. After a sector is protected, it cannot be unprotected by user code. The Flash Sector Protect Register is cleared after reset and any previously written protection values is lost. User code must write this register in their initialization routine if they want to enable sector protection.

The Flash Sector Protect Register shares its Register File address with the Page Select Register. The Flash Sector Protect Register is accessed by writing the Flash Control Register with 5EH. After the Flash Sector Protect Register is selected, it can be accessed at the Page Select Register address. When user code writes the Flash Sector Protect Register,

## Flash Frequency High and Low Byte Registers

The Flash Frequency High and Low Byte registers, shown in Tables 76 and 77, combine to form a 16-bit value, FFREQ, to control timing for Flash program and erase operations. The 16-bit binary Flash frequency value must contain the system clock frequency (in kHz) and is calculated using the following equation:

 $FFREQ[15:0] = \{FFREQH[7:0], FFREQL[7:0]\} = \frac{System Clock Frequency}{1000}$ 

**Caution:** Flash programming and erasure is not supported for system clock frequencies below 10kHz or above 20MHz. The Flash Frequency High and Low Byte registers must be loaded with the correct value to ensure proper operation of the device.

| Bit     | 7           | 6 | 5   | 4       | 3 | 2   | 1   | 0   |  |  |  |

| Note: The variation is       | about 30%.                             |  |  |  |

#### Table 90. ClkFlt Delay Control Definition

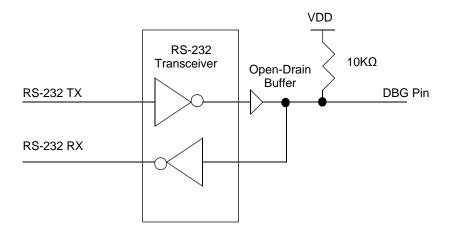

Figure 22. Interfacing the On-Chip Debugger's DBG Pin with an RS-232 Interface, #2 of 2

## **DEBUG Mode**

The operating characteristics of the devices in DEBUG Mode are:

- The eZ8 CPU fetch unit stops, idling the eZ8 CPU, unless directed by the OCD to execute specific instructions
- The system clock operates, unless the device is in STOP Mode
- All enabled on-chip peripherals operate, unless the device is in STOP Mode
- Automatically exits HALT Mode
- Constantly refreshes the Watchdog Timer, if enabled

## **Entering DEBUG Mode**

- The device enters DEBUG Mode after the eZ8 CPU executes a Breakpoint (BRK) instruction
- If the DBG pin is held low during the most recent clock cycle of system reset, the device enters DEBUG Mode on exiting system reset

## **Exiting DEBUG Mode**

The device exits DEBUG Mode following any of these operations:

- Clearing the DBGMODE bit in the OCD Control Register to 0
- Power-On Reset
- Voltage Brown-Out reset

## Figures 29 and 30 provide information about each of the eZ8 CPU instructions.

Figure 29. First Op Code Map

Upper Nibble (Hex)

## **General Purpose I/O Port Output Timing**

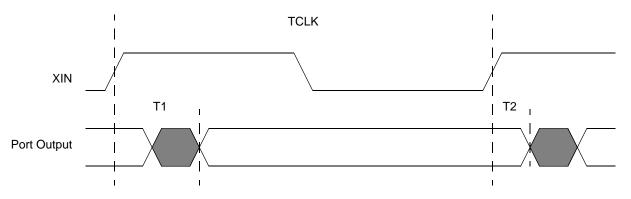

Figure 34 and Table 125 provide timing information for the GPIO port pins.

|                |                                     | Delay (ns) |         |  |  |  |  |  |
|----------------|-------------------------------------|------------|---------|--|--|--|--|--|
| Parameter      | Abbreviation                        | Minimum    | Maximum |  |  |  |  |  |
| GPIO Port Pins |                                     |            |         |  |  |  |  |  |
| T <sub>1</sub> | XIN Rise to Port Output Valid Delay | _          | 15      |  |  |  |  |  |
| T <sub>2</sub> | XIN Rise to Port Output Hold Time   | 2          | _       |  |  |  |  |  |

### Table 125. GPIO Port Output Timing

207

Table 129 lists the pin count by package.

| Package | Pin Count    |    |
|---------|--------------|----|
|         | 20           | 28 |
| PDIP    | $\checkmark$ |    |
| QFN     | $\checkmark$ |    |
| SOIC    | $\checkmark$ |    |
| SSOP    | $\checkmark$ |    |
