Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

The maximum overshoot duration is specified as a high-time percentage over the lifetime of the device. A DC signal is equivalent to 100% of the duty-cycle.

6.2.2.1 Power-Supply Ramp Times

The following table shows the allowable power-up ramp times. Times shown correspond to the ramp of the supply from 0 V to the minimum recommended voltage as specified in the section Recommended Operating Conditions (see page 6). All supplies must rise and fall monotonically.

Table 10 • Power-Supply Ramp Times

Parameter	Symbol	Min	Max	Unit
FPGA core supply	V_{DD}	0.2	50	ms
Transceiver core supply	V_{DDA}	0.2	50	ms
Must connect to 1.8 V supply	V_{DD18}	0.2	50	ms
Must connect to 2.5 V supply	V_{DD25}	0.2	50	ms
Must connect to 2.5 V supply	V_{DDA25}	0.2	50	ms
HSIO bank I/O power supplies	$V_{DDI[0,1,6,7]}$	0.2	50	ms
GPIO bank I/O power supplies	$V_{DDI[2,4,5]}$	0.2	50	ms
Bank 3 dedicated I/O buffers (GPIO)	V_{DDI3}	0.2	50	ms
GPIO bank auxiliary power supplies	$V_{DDAUX[2,4,5]}$	0.2	50	ms
Transceiver reference clock supply	$V_{DD\_XCVR\_CLK}$	0.2	50	ms
Global V_{REF} for transceiver reference clocks	$XCVR_{VREF}$	0.2	50	ms

Note: For proper operation of programming recovery mode, if a VDD supply brownout occurs during programming, a minimum supply ramp down time for only the VDD supply is recommended to be 10 ms or longer by using a programmable regulator or on-board capacitors.

6.2.2.2 Hot Socketing

The following table lists the hot-socketing DC characteristics over recommended operating conditions.

Table 11 • Hot Socketing DC Characteristics over Recommended Operating Conditions

Parameter	Symbol	Min	Typ	Max	Unit	Condition
Current per transceiver Rx input pin (P or N single-ended)[1, 2]	XCVRRX_HS			±4	mA	V_{DDA} = 0 V
Current per transceiver Tx output pin (P or N single-ended)[3]	XCVRTX_HS			±10	mA	V_{DDA} = 0 V
Current per transceiver reference clock input pin (P or N single-ended)[4]	XCVRREF_HS			±1	mA	$V_{DD\_XCVR\_CLK}$ = 0 V
Current per GPIO pin (P or N single-ended)[5]	I_{GPIO_HS}			±1	mA	V_{DDIx} = 0 V
Current per HSIO pin (P or N single-ended)						Hot socketing is not supported in HSIO.

1. Assumes that the device is powered-down, all supplies are grounded, AC-coupled interface, and input pin pairs are driven by a CML driver at the maximum amplitude (1 V pk–pk) that is toggling at any rate with PRBS7 data.
2. Each P and N transceiver input has less than the specified maximum input current.
3. Each P and N transceiver output is connected to a 40 Ω resistor (50 Ω CML termination – 20% tolerance) to the maximum allowed output voltage (V_{DDAmax} + 0.3 V = 1.4 V) through an AC-coupling capacitor with all PolarFire device supplies grounded. This shows the current for a worst-case DC coupled interface. As an AC-coupled interface, the output signal will settle at ground and no hot socket current will be seen.
4. $V_{DD\_XCVR\_CLK}$ is powered down and the device is driven to –0.3 V < V_{IN} < $V_{DD\_XCVR\_CLK}$.
5. V_{DDIx} is powered down and the device is driven to –0.3 V < V_{IN} < GPIO V_{DDImax}.

Note: The following dedicated pins do not support hot socketing: TMS, TDI, TRSTB, DEVRST_N, and FF_EXIT_N. Weak pull-up (as specified in GPIO) is always enabled.

1. Minimum time for high or low pulse width.
2. Maximum jitter the PLL can tolerate without losing lock.
3. Default bandwidth setting of BW_PROP_CTRL = "01" for Integer and Fraction modes leads to the typical estimated bandwidth. This bandwidth can be lowered by setting BW_PROP_CTRL = "00" and can be increased if BW_PROP_CTRL = "10" and will be at the highest value if BW_PROP_CTRL = "11".
4. Maximum (±3-Sigma) phase error between any two outputs with nominally aligned phases.
5. Input clock cycle is REFDIV/F_{REF}. For example, F_{REF} = 25 MHz, REFDIV = 1, lock time = 10.0 (assumes LOCKCOUNTSEL setting = 4'd8 (256 cycles)).
6. Unlock occurs if two cycle slip within LOCKCOUNT/4 PFD cycles.
7. Maximum propagation delay of external feedback path in deskew mode.
8. Programmable capability for depth of down spread or center spread modulation.
9. Programmable modulation rate based on the modulation divider setting (1 to 63).

Note: In order to meet all data sheet specifications, the PLL must be programmed such that the PLL Loop Bandwidth < (0.0017 * VCO Frequency) – 0.4863 MHz. The Libero PLL configuration tool will enforce this rule when creating PLL configurations.

- Standalone verify checks the programming margin on both the P and N gates of the push-pull cell.
- Digest checks only the P side of the push-pull gate. However, the push-pull gates work in tandem. Digest check is recommended if users believe they will exceed the 2,000-hour verify time specification.

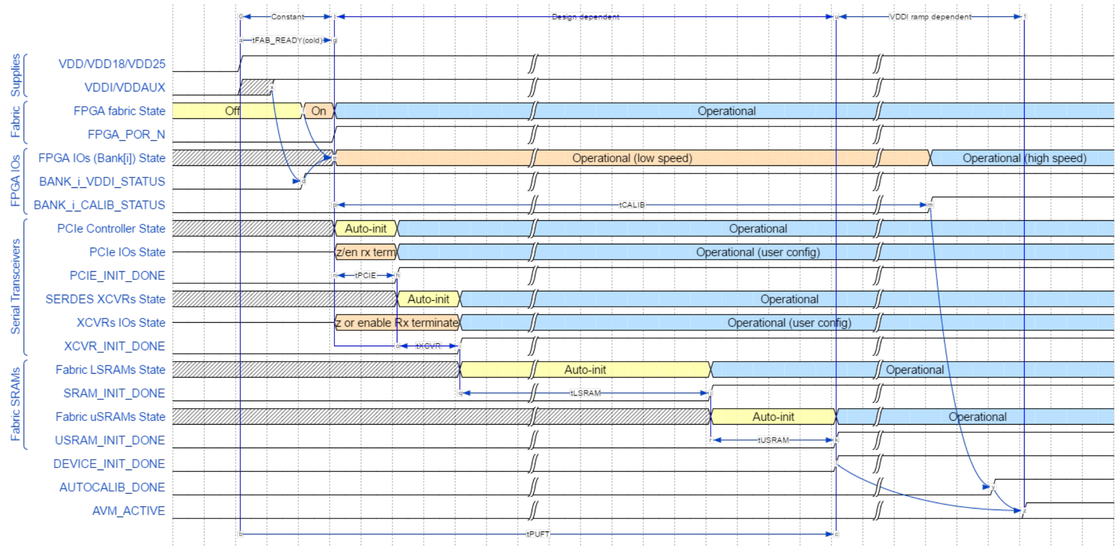
7.9 Power-Up to Functional Timing

Microsemi non-volatile FPGA technology offers the fastest boot-time of any mid-range FPGA in the market. The following tables describes both cold-boot (from power-on) and warm-boot (assertion of DEVRST_N pin or assertion of reset from the tamper macro) timing. The power-up diagrams assume all power supplies to the device are stable.

7.9.1 Power-On (Cold) Reset Initialization Sequence

The following cold reset timing diagram shows the initialization sequencing of the device.

Figure 5 • Cold Reset Timing



Notes:

- The previous diagram showsthe case where VDDI/VDDAUX of I/O banks are powered either before or sufficiently soon after VDD/VDD18/VDD25 that the I/O bank enable time is measured from the assertion time of VDD/VDD18/VDD25 (that is, the PUFT specification). If VDDI/VDDAUX of I/O banks are powered sufficiently after VDD/VDD18/VDD25, then the I/O bank enable time is measured from the assertion of VDDI/VDDAUX and is not specified by the PUFT specification. In this case, I/O operation is indicated by the assertion of BANK_i_VDDI_STATUS, rather than being measured relative to FABRIC_POR_N negation.
- AUTOCALIB_DONE assertion indicates the completion of calibration for any I/O banks specified by the user for auto-calibration. AUTOCALIB_DONE asserts independently of DEVICE_INIT_DONE. It may assert before or after DEVICE_INIT_DONE and is determined by the following:
  - How long after VDD/VDD18/VDD25 that VDDI/VDDAUX are powered on. Note that if any of the user-specified I/O banks are not powered on within the auto-calibration timeout window, then AUTOCALIB_DONE doesn't assert until after this timeout.
  - The specified ramp times of VDDI of each I/O bank designated for auto-calibration.
  - How much auto-initialization is to be performed for the PCIe, SERDES transceivers, and fabric LSRAMs.
- If any of the I/O banks specified for auto-calibration do not have their VDDI/VDDAUX powered on within the auto-calibration timeout window, then it will be approximately auto-calibrated whenever VDDI/VDDAUX is subsequently powered on. To obtain an accurate calibration however, on such IO banks, it is necessary to initiate a re-calibration (using CALIB_START from fabric).
- AVM_ACTIVE only asserts if avionics mode is being used. It is asserted when the later of DEVICE_INIT_DONE or AUTOCALIB_DONE assert.

7.9.2 Warm Reset Initialization Sequence

The following warm reset timing diagram shows the initialization sequencing of the device when either DEVRST_N or TAMPER_RESET_DEVICE signals are asserted.

Table 101 • Cold and Warm Boot

Parameter	Symbol	Min	Typ	Max	Unit	Condition
The time from T_{FAB_READY} to ready to program through JTAG/SPI-Slave		0	0	0	ms	
The time from T_{FAB_READY} to auto-update start			T_{PUF_OVHD}[1]	T_{PUF_OVHD}[1]	ms	
The time from T_{FAB_READY} to programming recovery start			T_{PUF_OVHD}[1]	T_{PUF_OVHD}[1]	ms	
The time from T_{FAB_READY} to the tamper flags being available	T_{TAMPER_READY}	0	0	0	ms	
The time from T_{FAB_READY} to the Athena Crypto co-processor being available (for S devices only)	T_{CRYPTO_READY}	0	0	0	ms	

1. Programming depends on the PUF to power up. Refer to T_{PUF_OVHD} at section Secure NVM Performance (see page 58).

7.9.8 I/O Calibration

The following tables specify the initial I/O calibration time for the fastest and slowest supported VDDI ramp times of 0.2 ms to 50 ms, respectively. This only applies to I/O banks specified by the user to be auto-calibrated.

Table 102 • I/O Initial Calibration Time (TCALIB)

Ramp Time	Min (ms)	Max (ms)	Condition
0.2 ms	0.98	2.63	Applies to HSIO and GPIO banks
50 ms	41.62	62.19	Applies to HSIO and GPIO banks

Notes:

- The user may specify any VDDI ramp time in the range specified above. The nominal initial calibration time is given by the specified VDDI ramp time plus 2 ms.
- In order for IO calibration to start, VDDI and VDDAUX of the I/O bank must be higher than the trip point levels specified in I/O-Related Supplies (see page 66).

Table 103 • I/O Fast Recalibration Time (TRECALIB)

I/O Type	Min (ms)	Typ (ms)	Max (ms)	Condition
GPIO bank	0.16	0.20	0.24	GPIO configured for 3.3 V operation
HSIO bank	0.20	0.25	0.30	HSIO configured for 1.8 V operation

Note: In order to obtain fast re-calibration, the user must assert the relevant clock request signal from the FPGA fabric to the I/O bank controller.

The following table describes the time to enter Flash*Freeze Mode and to exit Flash*Freeze mode.
