Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

1. F_{SKEWB} is the worst-case clock-tree skew observable between sequential I/O elements. Clock-tree skew is significantly smaller at I/O registers close to each other and fed by the same or adjacent clock-tree branches. Use the Microsemi Timing Analyzer tool to evaluate clock skew specific to the design.
2. Parameters listed in this table correspond to the worst-case duty cycle distortion observable at the I/O flip flops. IBIS should be used to calculate any additional duty cycle distortion that might be caused by asymmetrical rise/fall times for any I/O standard.

1. Minimum time for high or low pulse width.
2. Maximum jitter the PLL can tolerate without losing lock.
3. Default bandwidth setting of BW_PROP_CTRL = "01" for Integer and Fraction modes leads to the typical estimated bandwidth. This bandwidth can be lowered by setting BW_PROP_CTRL = "00" and can be increased if BW_PROP_CTRL = "10" and will be at the highest value if BW_PROP_CTRL = "11".
4. Maximum (±3-Sigma) phase error between any two outputs with nominally aligned phases.
5. Input clock cycle is REFDIV/F_{REF}. For example, F_{REF} = 25 MHz, REFDIV = 1, lock time = 10.0 (assumes LOCKCOUNTSEL setting = 4'd8 (256 cycles)).
6. Unlock occurs if two cycle slip within LOCKCOUNT/4 PFD cycles.
7. Maximum propagation delay of external feedback path in deskew mode.
8. Programmable capability for depth of down spread or center spread modulation.
9. Programmable modulation rate based on the modulation divider setting (1 to 63).

Note: In order to meet all data sheet specifications, the PLL must be programmed such that the PLL Loop Bandwidth < (0.0017 * VCO Frequency) – 0.4863 MHz. The Libero PLL configuration tool will enforce this rule when creating PLL configurations.

7.9.4 Design Dependence of T PUFT and T WRFT

Some phases of the device initialization are user design-dependent, as the device automatically initializes certain resources to user-specified configurations if those resources are used in the design. It is necessary to compute the overall power-up to functional time by referencing the following tables and adding the relevant phases, according to the design configuration. The following equation refers to timing parameters specified in the above timing diagrams. Please note T_{PCIE} , T_{XCVR}, T_{LSRAM}, and T_{USRAM} can be found in the PolarFire FPGA device power-up and resets user guide UG0725.

$T_{PUFT} = T_{FAB\_READY(cold)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$

$T_{WRFT} = T_{FAB\_READY(warm)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$

Note: T_{PCIE}, T_{XCVR}, T_{LSRAM}, T_{USRAM}, and T_{CALIB} are common to both cold and warm reset scenarios.

Auto-initialization of FPGA (if required) occurs in parallel with I/O calibration. The device may be considered fully functional only when the later of these two activities has finished, which may be either one, depending on the configuration, as may be calculated from the following tables. Note that I/O calibration may extend beyond T_{PUFT} (as I/O calibration process is independent of main device power-on and is instead dependent on I/O bank supply relative power-on time and ramp times). The previous timing diagram for power-on initialization shows the earliest that I/Os could be enabled, if the I/O power supplies are powered on before or at the same time as the main supplies.

7.9.5 Cold Reset to Fabric and I/Os (Low Speed) Functional

The following table specifies the minimum, typical, and maximum times from the power supplies reaching the above trip point levels until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub 400 MHz) operation.

Table 99 • Cold Boot

Power-On (Cold) Reset to Fabric and I/O Operational	Min	Typ	Max	Unit
Time when input pins start working – $T_{IN\_ACTIVE(cold)}$	1.17	4.51	7.84	ms
Time when weak pull-ups are enabled – $T_{PU\_PD\_ACTIVE(cold)}$	1.17	4.51	7.84	ms
Time when fabric is operational – $T_{FAB\_READY(cold)}$	1.20	4.54	7.87	ms
Time when output pins start driving – $T_{OUT\_ACTIVE(cold)}$	1.22	4.56	7.89	ms

7.9.6 Warm Reset to Fabric and I/Os (Low Speed) Functional

The following table specifies the minimum, typical, and maximum times from the negation of the warm reset event until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub 400 MHz) operation.

Table 100 • Warm Boot

Warm Reset to Fabric and I/O Operational	Min	Typ	Max	Unit
Time when input pins start working – $T_{IN\_ACTIVE(warm)}$	0.91	1.76	2.62	ms

Time when output pins start driving – $T_{OUT\_ACTIVE(warm)}$	0.96	1.81	2.67	ms

7.9.7 Miscellaneous Initialization Parameters

In the following table, T_{FAB_READY} refers to either $T_{FAB\_READY(cold)}$ or $T_{FAB\_READY(warm)}$ as specified in the previous tables, depending on whether the initialization is occurring as a result of a cold or warm reset, respectively.

Table 101 • Cold and Warm Boot

Parameter	Symbol	Min	Typ	Max	Unit	Condition
The time from T_{FAB_READY} to ready to program through JTAG/SPI-Slave		0	0	0	ms	
The time from T_{FAB_READY} to auto-update start			T_{PUF_OVHD}[1]	T_{PUF_OVHD}[1]	ms	
The time from T_{FAB_READY} to programming recovery start			T_{PUF_OVHD}[1]	T_{PUF_OVHD}[1]	ms

The time from T_{FAB_READY} to the Athena Crypto co-processor being available (for S devices only)	T_{CRYPTO_READY}	0	0	0	ms	

1. Programming depends on the PUF to power up. Refer to T_{PUF_OVHD} at section Secure NVM Performance (see page 58).

7.9.8 I/O Calibration

The following tables specify the initial I/O calibration time for the fastest and slowest supported VDDI ramp times of 0.2 ms to 50 ms, respectively. This only applies to I/O banks specified by the user to be auto-calibrated.

Table 102 • I/O Initial Calibration Time (TCALIB)

Ramp Time	Min (ms)	Max (ms)	Condition
0.2 ms	0.98	2.63	Applies to HSIO and GPIO banks
50 ms	41.62	62.19	Applies to HSIO and GPIO banks

Notes:

- The user may specify any VDDI ramp time in the range specified above. The nominal initial calibration time is given by the specified VDDI ramp time plus 2 ms.
- In order for IO calibration to start, VDDI and VDDAUX of the I/O bank must be higher than the trip point levels specified in I/O-Related Supplies (see page 66).

HSIO bank	0.20	0.25	0.30	HSIO configured for 1.8 V operation

Note: In order to obtain fast re-calibration, the user must assert the relevant clock request signal from the FPGA fabric to the I/O bank controller.
