Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

1. Minimum time for high or low pulse width.
2. Maximum jitter the PLL can tolerate without losing lock.
3. Default bandwidth setting of BW_PROP_CTRL = "01" for Integer and Fraction modes leads to the typical estimated bandwidth. This bandwidth can be lowered by setting BW_PROP_CTRL = "00" and can be increased if BW_PROP_CTRL = "10" and will be at the highest value if BW_PROP_CTRL = "11".
4. Maximum (±3-Sigma) phase error between any two outputs with nominally aligned phases.
5. Input clock cycle is REFDIV/F_{REF}. For example, F_{REF} = 25 MHz, REFDIV = 1, lock time = 10.0 (assumes LOCKCOUNTSEL setting = 4'd8 (256 cycles)).
6. Unlock occurs if two cycle slip within LOCKCOUNT/4 PFD cycles.
7. Maximum propagation delay of external feedback path in deskew mode.
8. Programmable capability for depth of down spread or center spread modulation.
9. Programmable modulation rate based on the modulation divider setting (1 to 63).

Note: In order to meet all data sheet specifications, the PLL must be programmed such that the PLL Loop Bandwidth < (0.0017 * VCO Frequency) – 0.4863 MHz. The Libero PLL configuration tool will enforce this rule when creating PLL configurations.

Notes:

- The maximum number of device digest cycles is 100K.
- Digests are operational only over the –40 °C to 100 °C temperature range.
- After a program cycle, an additional N digests cycles are allowed with the resultant retention characteristics for the total operating and storage temperature shown.
- Retention is specified for total device storage and operating temperature.
- All temperatures are junction temperatures (T_J).
- Example 1—500 digests cycles are performed between programming cycles. N = 500. The operating conditions are –40 °C to 85 °C T_J. 501 programming cycles have occurred. The retention under these operating conditions is 20 × LF = 20 × .8 = 16 years.
- Example 2—one programming cycle has occurred, N = 1500 digest cycles have occurred. Temperature range is –40 °C to 100 °C. The resultant retention is 10 × LF or 10 years over the industrial temperature range.

Notes:

- Standalone verify is limited to 2,000 total device hours ove r the industrial –40 °C to 100 °C temperature.
- Use the digest system service, for verify device time more than 2,000 hours.
- Standalone verify checks the programming margin on both the P and N gates of the push-pull cell.
- Digest checks only the P side of the push-pull gate. However, the push-pull gates work in tandem. Digest check is recommended if users believe they will exceed the 2,000-hour verify time specification.

7.8.4 Tamper Detectors

The following section describes tamper detectors.

Table 91 • ADC Conversion Rate

Parameter	Description	Min	Typ[1]	Max
T_{CONV1}	Time from enable changing from zero to non-zero value to first conversion completes. Minimum value applies when POWEROFF = 0.	420 µs		470 µs
T_{CONVN}	Time between subsequent channel conversions.		480 µs	
T_{SETUP}	Data channel and output to valid asserted. Data is held until next conversion completes, that is >480 µs.	0 ns		
T_{VALID}[2]	Width of the valid pulse.	1.625 µs		2 µs
T_{RATE}	Time from start of first set of conversions to the start of the next set. Can be considered as the conversion rate. Is set by the conversion rate parameter.	480 µs	Rate × 32 µs	8128 µs

1. Min, typ, and max refer to variation due to functional configuration and the raw TVS value. The actual internal correction time will vary based on the raw TVS value.
2. The pulse width varies depending on the time taken to complete the internal calibration multiplication, this can be up to 375 ns.

Note: Once the TVS block is active, the enable signal is sampled 25 ns before the falling edge of valid. The next enabled channel in the sequence 0-1-2-3 is started; that is, if channel 0 has just completed and only channels 0 and 3 are enabled, the next channel will be 3. When all the enabled channels in the sequence 0-1-2-3 are completed, the TVS waits for the conversion rate timer to expire. The enable signal may be changed at any time if it changes to 4'b0000 while valid is asserted (and 25 ns before valid is de-asserted), then no further conversions will be started.

7.9.4 Design Dependence of T PUFT and T WRFT

Some phases of the device initialization are user design-dependent, as the device automatically initializes certain resources to user-specified configurations if those resources are used in the design. It is necessary to compute the overall power-up to functional time by referencing the following tables and adding the relevant phases, according to the design configuration. The following equation refers to timing parameters specified in the above timing diagrams. Please note T_{PCIE} , T_{XCVR}, T_{LSRAM}, and T_{USRAM} can be found in the PolarFire FPGA device power-up and resets user guide UG0725.

$T_{PUFT} = T_{FAB\_READY(cold)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$

$T_{WRFT} = T_{FAB\_READY(warm)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$

Note: T_{PCIE}, T_{XCVR}, T_{LSRAM}, T_{USRAM}, and T_{CALIB} are common to both cold and warm reset scenarios.

Auto-initialization of FPGA (if required) occurs in parallel with I/O calibration. The device may be considered fully functional only when the later of these two activities has finished, which may be either one, depending on the configuration, as may be calculated from the following tables. Note that I/O calibration may extend beyond T_{PUFT} (as I/O calibration process is independent of main device power-on and is instead dependent on I/O bank supply relative power-on time and ramp times). The previous timing diagram for power-on initialization shows the earliest that I/Os could be enabled, if the I/O power supplies are powered on before or at the same time as the main supplies.

7.9.5 Cold Reset to Fabric and I/Os (Low Speed) Functional

The following table specifies the minimum, typical, and maximum times from the power supplies reaching the above trip point levels until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub 400 MHz) operation.

7.9.6 Warm Reset to Fabric and I/Os (Low Speed) Functional

The following table specifies the minimum, typical, and maximum times from the negation of the warm reset event until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub 400 MHz) operation.

7.9.7 Miscellaneous Initialization Parameters

In the following table, T_{FAB_READY} refers to either $T_{FAB\_READY(cold)}$ or $T_{FAB\_READY(warm)}$ as specified in the previous tables, depending on whether the initialization is occurring as a result of a cold or warm reset, respectively.
