Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

6.2.2.2 Hot Socketing

Table 11 • Hot Socketing DC Characteristics over Recommended Operating Conditions

Parameter	Symbol	Min	Typ	Max	Unit	Condition
Current per transceiver Rx input pin (P or N single-ended)[1, 2]	I_{XCVRRX_HS}			±4	mA	V_{DDA} = 0 V
Current per transceiver Tx output pin (P or N single-ended)[3]	I_{XCVRTX_HS}			±10	mA	V_{DDA} = 0 V
Current per transceiver reference clock input pin (P or N single-ended)[4]	$I_{XCVRREF\_HS}$			±1	mA	$V_{DD\_XCVR\_CLK}$ = 0 V
Current per GPIO pin (P or N single-ended)[5]	I_{GPIO_HS}			±1	mA	V_{DDIx} = 0 V
Current per HSIO pin (P or N single-ended)						Hot socketing is not supported in HSIO.

1. Assumes that the device is powered-down, all supplies are grounded, AC-coupled interface, and input pin pairs are driven by a CML driver at the maximum amplitude (1 V pk–pk) that is toggling at any rate with PRBS7 data.
2. Each P and N transceiver input has less than the specified maximum input current.
3. Each P and N transceiver output is connected to a 40 Ω resistor (50 Ω CML termination – 20% tolerance) to the maximum allowed output voltage (V_{DDAmax} + 0.3 V = 1.4 V) through an AC-coupling capacitor with all PolarFire device supplies grounded. This shows the current for a worst-case DC coupled interface. As an AC-coupled interface, the output signal will settle at ground and no hot socket current will be seen.
4. $V_{DD\_XCVR\_CLK}$ is powered down and the device is driven to $–0.3\ V < V_{IN} < V_{DD\_XCVR\_CLK}$.
5. V_{DDIx} is powered down and the device is driven to $–0.3\ V < V_{IN} <$ GPIO V_{DDImax}.

–40 °C to 100 °C	500	1
–40 °C to 85 °C	1000	0.8
–40 °C to 55 °C	2000	0.6

Notes:

- The maximum number of device digest cycles is 100K.
- Digests are operational only over the –40 °C to 100 °C temperature range.
- After a program cycle, an additional N digests cycles are allowed with the resultant retention characteristics for the total operating and storage temperature shown.
- Retention is specified for total device storage and operating temperature.
- All temperatures are junction temperatures (T_J).
- Example 1—500 digests cycles are performed between programming cycles. N = 500. The operating conditions are –40 °C to 85 °C T_J. 501 programming cycles have occurred. The retention under these operating conditions is 20 × LF = 20 × .8 = 16 years.
- Example 2—one programming cycle has occurred, N = 1500 digest cycles have occurred. Temperature range is –40 °C to 100 °C. The resultant retention is 10 × LF or 10 years over the industrial temperature range.

7.8.4 Tamper Detectors

The following section describes tamper detectors.

Table 91 • ADC Conversion Rate

Parameter	Description	Min	Typ[1]	Max
T_{CONV1}	Time from enable changing from zero to non-zero value to first conversion completes. Minimum value applies when POWEROFF = 0.	420 µs		470 µs
T_{CONVN}	Time between subsequent channel conversions.		480 µs	
T_{SETUP}	Data channel and output to valid asserted. Data is held until next conversion completes, that is >480 µs.	0 ns		
T_{VALID}[2]	Width of the valid pulse.	1.625 µs		2 µs
T_{RATE}	Time from start of first set of conversions to the start of the next set. Can be considered as the conversion rate. Is set by the conversion rate parameter.	480 µs	Rate × 32 µs	8128 µs

1. Min, typ, and max refer to variation due to functional configuration and the raw TVS value. The actual internal correction time will vary based on the raw TVS value.
2. The pulse width varies depending on the time taken to complete the internal calibration multiplication, this can be up to 375 ns.

Note: Once the TVS block is active, the enable signal is sampled 25 ns before the falling edge of valid. The next enabled channel in the sequence 0-1-2-3 is started; that is, if channel 0 has just completed and only channels 0 and 3 are enabled, the next channel will be 3. When all the enabled channels in the sequence 0-1-2-3 are completed, the TVS waits for the conversion rate timer to expire. The enable signal may be changed at any time if it changes to 4'b0000 while valid is asserted (and 25 ns before valid is de-asserted), then no further conversions will be started.

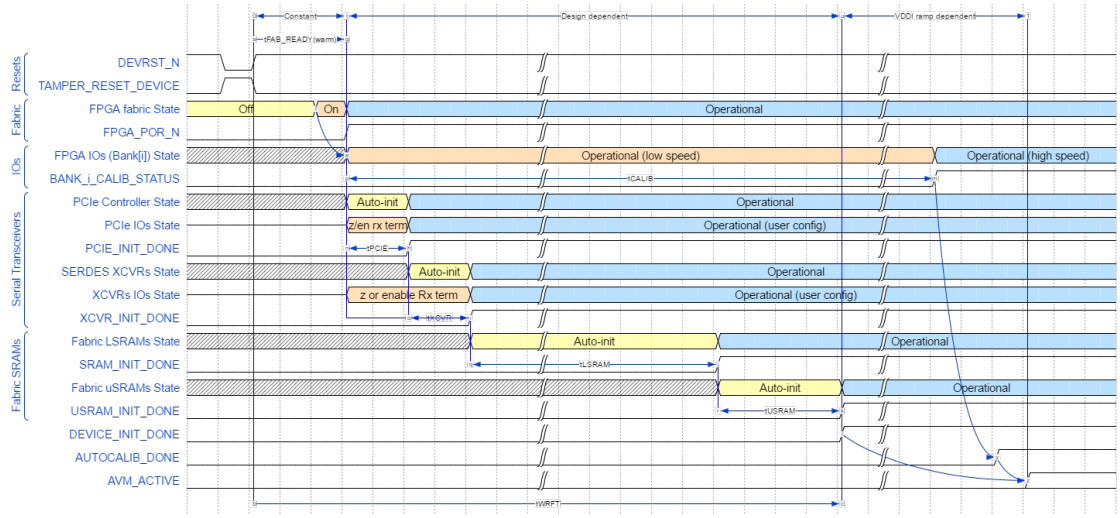
Figure 6 • Warm Reset Timing



7.9.3 Power-On Reset Voltages

7.9.3.1 Main Supplies

The start of power-up to functional time (T_{PUFT}) is defined as the point at which the latest of the main supplies (VDD, VDD18, VDD25) reach the reference voltage levels specified in the following table. This starts the process of releasing the reset of the device and powering on the FPGA fabric and IOs.

Table 97 • POR Ref Voltages

Supply	Power-On Reset Start Point (V)	Note
VDD	0.95	Applies to both 1.0 V and 1.05 V operation.
VDD18	1.71	
VDD25	2.25	

7.9.3.2 I/O-Related Supplies

For the I/Os to become functional (for low speed, sub 400 MHz operation), the (per-bank) I/O supplies (VDDI, VDDAUX) must reach the trip point voltage levels specified in the following table and the main supplies above must also be powered on.

Table 98 • I/O-Related Supplies

Supply	I/O Power-Up Start Point (V)
VDDI	0.85
VDDAUX	1.6

There are no sequencing requirements for the power supplies. However, VDDI3 and must be valid at same time as the main supplies. The other IO supplies (VDDI, VDDAUX) have no effect on power-up of FPGA fabric (that is, the fabric still powers up even if the IO supplies of some IO banks remain powered off).

7.9.4 Design Dependence of T PUFT and T WRFT

Some phases of the device initialization are user design-dependent, as the device automatically initializes certain resources to user-specified configurations if those resources are used in the design. It is necessary to compute the overall power-up to functional time by referencing the following tables and adding the relevant phases, according to the design configuration. The following equation refers to timing parameters specified in the above timing diagrams. Please note T_{PCIE} , T_{XCVR}, T_{LSRAM}, and T_{USRAM} can be found in the PolarFire FPGA device power-up and resets user guide UG0725.

$T_{PUFT} = T_{FAB\_READY(cold)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$

$T_{WRFT} = T_{FAB\_READY(warm)} + \max((T_{PCIE} + T_{XCVR} + T_{LSRAM} + T_{USRAM}), T_{CALIB})$

Note: T_{PCIE}, T_{XCVR}, T_{LSRAM}, T_{USRAM}, and T_{CALIB} are common to both cold and warm reset scenarios.

Auto-initialization of FPGA (if required) occurs in parallel with I/O calibration. The device may be considered fully functional only when the later of these two activities has finished, which may be either one, depending on the configuration, as may be calculated from the following tables. Note that I/O calibration may extend beyond T_{PUFT} (as I/O calibration process is independent of main device power-on and is instead dependent on I/O bank supply relative power-on time and ramp times). The previous timing diagram for power-on initialization shows the earliest that I/Os could be enabled, if the I/O power supplies are powered on before or at the same time as the main supplies.

7.9.5 Cold Reset to Fabric and I/Os (Low Speed) Functional

The following table specifies the minimum, typical, and maximum times from the power supplies reaching the above trip point levels until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub 400 MHz) operation.

Table 99 • Cold Boot

Power-On (Cold) Reset to Fabric and I/O Operational	Min	Typ	Max	Unit
Time when input pins start working – $T_{IN\_ACTIVE(cold)}$	1.17	4.51	7.84	ms
Time when weak pull-ups are enabled – $T_{PU\_PD\_ACTIVE(cold)}$	1.17	4.51	7.84	ms
Time when fabric is operational – $T_{FAB\_READY(cold)}$	1.20	4.54	7.87	ms
Time when output pins start driving – $T_{OUT\_ACTIVE(cold)}$	1.22	4.56	7.89	ms

7.9.6 Warm Reset to Fabric and I/Os (Low Speed) Functional

The following table specifies the minimum, typical, and maximum times from the negation of the warm reset event until the FPGA fabric is operational and the FPGA IOs are functional for low-speed (sub 400 MHz) operation.

Table 100 • Warm Boot

Warm Reset to Fabric and I/O Operational	Min	Typ	Max	Unit
Time when input pins start working – $T_{IN\_ACTIVE(warm)}$	0.91	1.76	2.62	ms
Time when weak pull-ups/pull-downs are enabled – $T_{PU\_PD\_ACTIVE(warm)}$	0.91	1.76	2.62	ms
Time when fabric is operational – $T_{FAB\_READY(warm)}$	0.94	1.79	2.65	ms
Time when output pins start driving – $T_{OUT\_ACTIVE(warm)}$	0.96	1.81	2.67	ms

7.9.7 Miscellaneous Initialization Parameters

In the following table, T_{FAB_READY} refers to either $T_{FAB\_READY(cold)}$ or $T_{FAB\_READY(warm)}$ as specified in the previous tables, depending on whether the initialization is occurring as a result of a cold or warm reset, respectively.
