Understanding Embedded - CPLDs (Complex Programmable Logic Devices)

Embedded - CPLDs, or Complex Programmable Logic Devices, are highly versatile digital logic devices used in electronic systems. These programmable components are designed to perform complex logical operations and can be customized for specific applications. Unlike fixed-function ICs, CPLDs offer the flexibility to reprogram their configuration, making them an ideal choice for various embedded systems. They consist of a set of logic gates and programmable interconnects, allowing designers to implement complex logic circuits without needing custom hardware.

The ispMACH5000VG devices also contain sysCLOCK Phase Locked Loops (PLLs) that provide designers with increased clocking flexibility. The PLLs can be used to synthesize new clocks for use on-chip or elsewhere within the system. They can also be used to deskew clocks, again both at the chip and system levels. A variable delay line capability further improves this and allows designers to retard or advance the clock in order to tune set-up and clock-to-out times for optimal results. The ispMACH 5000VG Family Selection Guide (Table 1) details the key attributes and packages for the ispMACH 5000VG devices.

ispMACH 5000VG Architecture

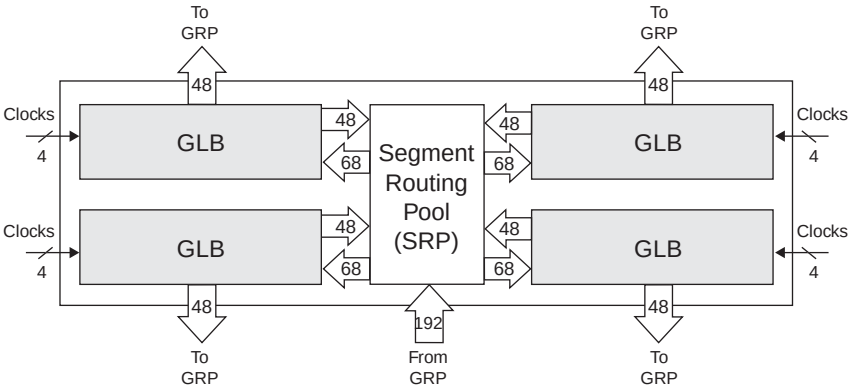
The ispMACH 5000VG Family of In-System Programmable High Density Logic Devices is based on segments containing four Generic Logic Blocks (GLBs) and a hierarchical routing pool (GRP) structure interconnecting the segments. A segment routing pool (SRP) connects each GLB in a segment allowing the maximum flexibility and speed.

Outputs from the GLBs drive the Segment Routing Pool (SRP) and the Global Routing Pool (GRP). Enhanced switching resources are provided to allow signals in the Segment Routing Pool to drive any or all the GLBs in the segment. Optimal switching is provided to allow all signals in the Global Routing Pool to be routed to any or all SRPs. This mechanism allows fast, efficient connections across the entire device.

Segment

Each segment contains four GLBs and a segment routing pool (SRP). Each GLB has 32 internal feedback outputs and 16 external feedback outputs, for a total of 48 outputs from each GLB feeding the SRP. The SRP contains up to 384 signals, 48 from each GLB and 192 from the GRP, with full routing capability. This routing scheme maximizes the flexibility and speed of the device without sacrificing the routing.

Figure 2. Segment



Generic Logic Block

Each GLB contains 32 macrocells and a fully populated, programmable AND-array with 160 logic product terms and three control product terms. The GLB has 68 inputs from the Segment Routing Pool, which are available in both true and complement form for every product term. The three control product terms are used for shared reset, clock and output enable functions. Figure 3 shows the structure of the GLB from the macrocell perspective. This is referred to as a macrocell slice. There are 32 macrocell slices per GLB.

AND-Array

The programmable AND-Array consists of 68 inputs and 163 output product terms. The 68 inputs from the SRP are used to form 136 lines in the AND-Array (true and complement of the inputs). Each line in the array can be connected to any of the 163 output product terms via a wired AND. Each of the 160 logic product terms feed the Dual-OR Array with the remaining three control product terms feeding the Shared PT Clock, Shared PT Reset and Shared PT OE. Every set of five product terms from the 160 logic product terms forms a product term cluster start-

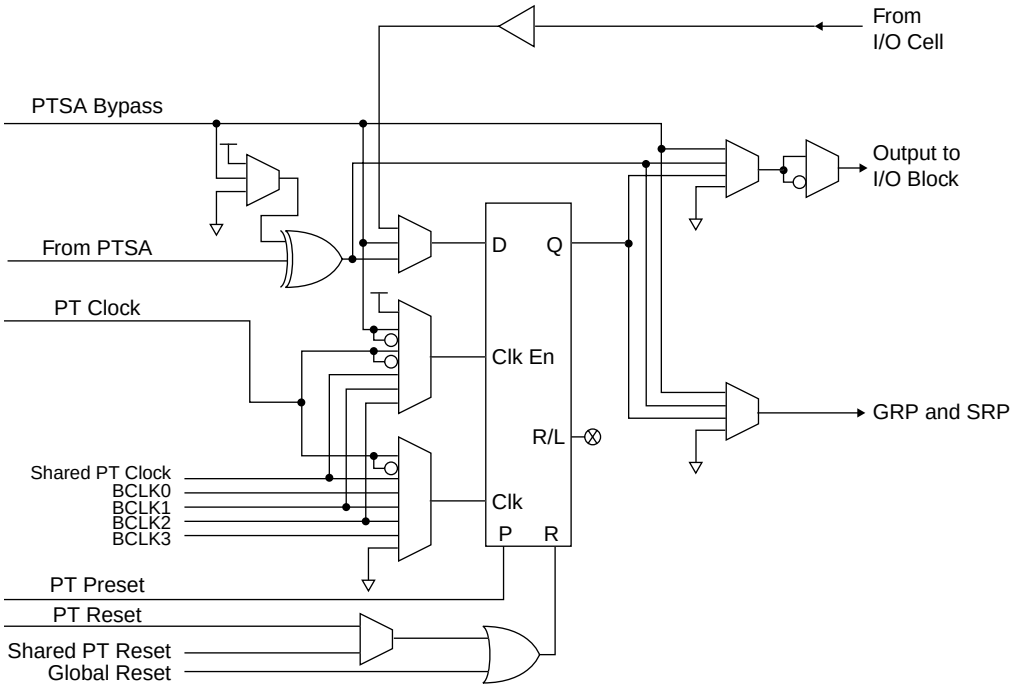
ing with PT0. There is one product term cluster for every macrocell in the GLB. In addition to the three control product terms, the first, third, fourth and fifth product terms of each cluster can be used as a PTOE (output macrocells only), PT Clock, PT Preset and PT Reset, respectively. Figure 4 is a graphical representation of the AND-Array.

Figure 7. Macrocell



I/O Cell

The I/O cell of the ispMACH 5000VG device provides a high degree of flexibility. It includes the sysIO feature and an enhanced output enable MUX for optimal performance both on- and off-chip. The sysIO feature allows I/O cells to be configured to different I/O standards, drive strengths and slew rates. The enhanced output enable MUX provides up to 14 different output enable choices per I/O cell.

The I/O cell contains an output enable (OE) MUX, a programmable tri-state output buffer, a programmable input buffer, a programmable pull-up resistor, a programmable pull-down resistor and a programmable bus-keeper latch. The I/O cell receives its input from its associated macrocell. The I/O cell has a feedback line to its associated macrocell and a direct path to the GRP and SRP.

The output enable (OE) MUX selects the OE signal per I/O cell. The inputs to the OE MUX are the four Shared PTOE signals, PTOE and the two GOE signals. The OE MUX also has the ability to choose either the true or inverse of each of these signals. The output of the OE MUX goes through a logical AND with the TOE signal to allow easy tri-stating of the outputs for testing purposes.

The four shared PTOE signals are derived from PT163 of each GLB in the segment. The PTOE signal is derived from the first product term in each macrocell cluster, which is directly routed to the OE MUX. Therefore, every I/O cell can have a different OE signal. Figure 8 is a graphical representation of the I/O cell.

Timing v.1.10

1. Timing numbers are based on default LVCMOS 3.3 I/O Buffers. Use timing adjusters provided to calculate timing for other standards.
2. Measured using standard switching circuit, assuming segment and global routing loading of 1, worst case PTSA loading and 1 output switching.
3. Pulse widths and clock widths less than minimum will cause unknown behavior.
4. Standard 16-bit counter using SRP feedback.

Timing Model

The task of determining the timing through the ispMACH 5000VG family, like any CPLD, is relatively simple. The timing model provided in Figure 11 shows the specific delay paths. Once the implementation of a given function is determined either conceptually or from the software report file, the delay path of the function can easily be determined from the timing model. The Lattice design tools report the timing delays based on the same timing model for a particular design. Note that the internal timing parameters are given for reference only, and are not tested. The external timing parameters are tested and guaranteed for every device. For more information on the timing model and usage, please refer to Technical Note TN1001: *ispMACH 5000VG Timing Model Design and Usage Guidelines.*

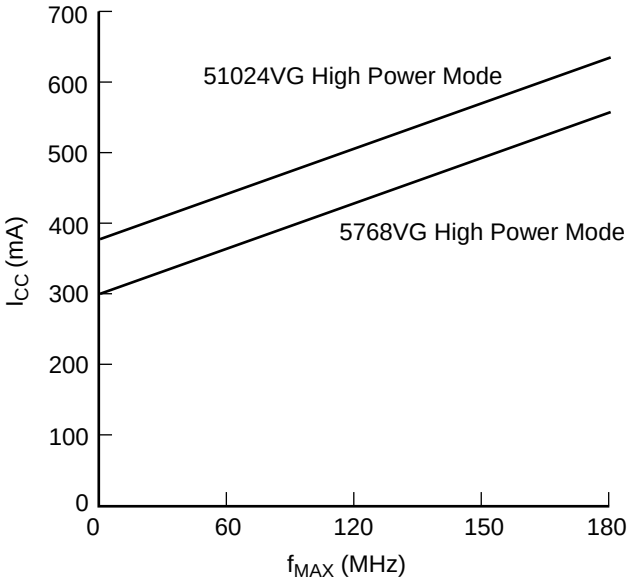
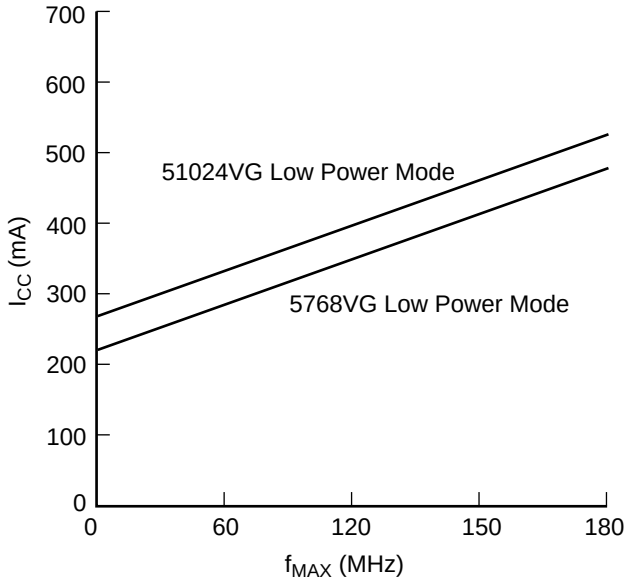
Power Consumption

ispMACH 5000VG Typical Power vs. Frequency

ispMACH 5000VG I_{CC} Curves at High Power Mode



ispMACH 5000VG I_{CC} Curves at Low Power Mode



Note: The devices are configured with maximum number of 16-bit counters, no PLL, typical current at 3.3V, 25° C.

Power Estimation Coefficients

Device	K0	K1	K2	K3	K4	K5	K6	I_{DC} (mA)	I_{DCO} (mA)
ispMACH 5768VG	0.0014	0.0014	0.054	1.5	0.152	0.105	5.0	65	20
ispMACH 51024VG	0.0014	0.0014	0.054	1.5	0.152	0.105	5.0	80	20

Note: For further information about the use of these coefficients, refer to Technical Note TN1002, *Power Estimation in ispMACH 5000VG Devices*.

K0 = average current per product term in high power/MHz
K1 = average current per product term in low power/MHz
K2 = average current per GRP line/MHz
K3 = average current per PLL/MHz
K4 = DC current per product terms in high power
K5 = DC current per product terms in low power
K6 = Static DC current per PLL
I_{DC} = Static device current with all product terms powered off
I_{DCO} = Static I/O bank current

Icc estimates are based on typical conditions (Vcc = 3.3V, room temperature) and an assumption of one GLB load on average exists. These values are for estimates only. Since the value of Icc is sensitive to operating conditions and the program in the device, the actual Icc should be verified.

Switching Test Conditions

Figure 12 shows the output test load that is used for AC testing. The specific values for resistance, capacitance, voltage, and other test conditions are shown in Table 3.

Figure 12. Output Test Load, LVTTL and LVCMOS Standards

Default LVCMOS 3.3 I/O (Z -> H)	∞	110	35pF	1.5V	3.0V
Default LVCMOS 3.3 I/O (Z -> L)	110	∞	35pF	1.5V	3.0V
Default LVCMOS 3.3 I/O (H -> Z)	∞	110	5pF	V_{OH} - 0.3	3.0V
Default LVCMOS 3.3 I/O (L -> Z)	110	∞	5pF	V_{OL} + 0.3	3.0V

Output test conditions for all other interfaces are determined by the respective standards. For further details, please refer to the following technical note:
