

Welcome to [E-XFL.COM](http://E-XFL.COM)

### What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

### Applications of "[Embedded - Microcontrollers](#)"

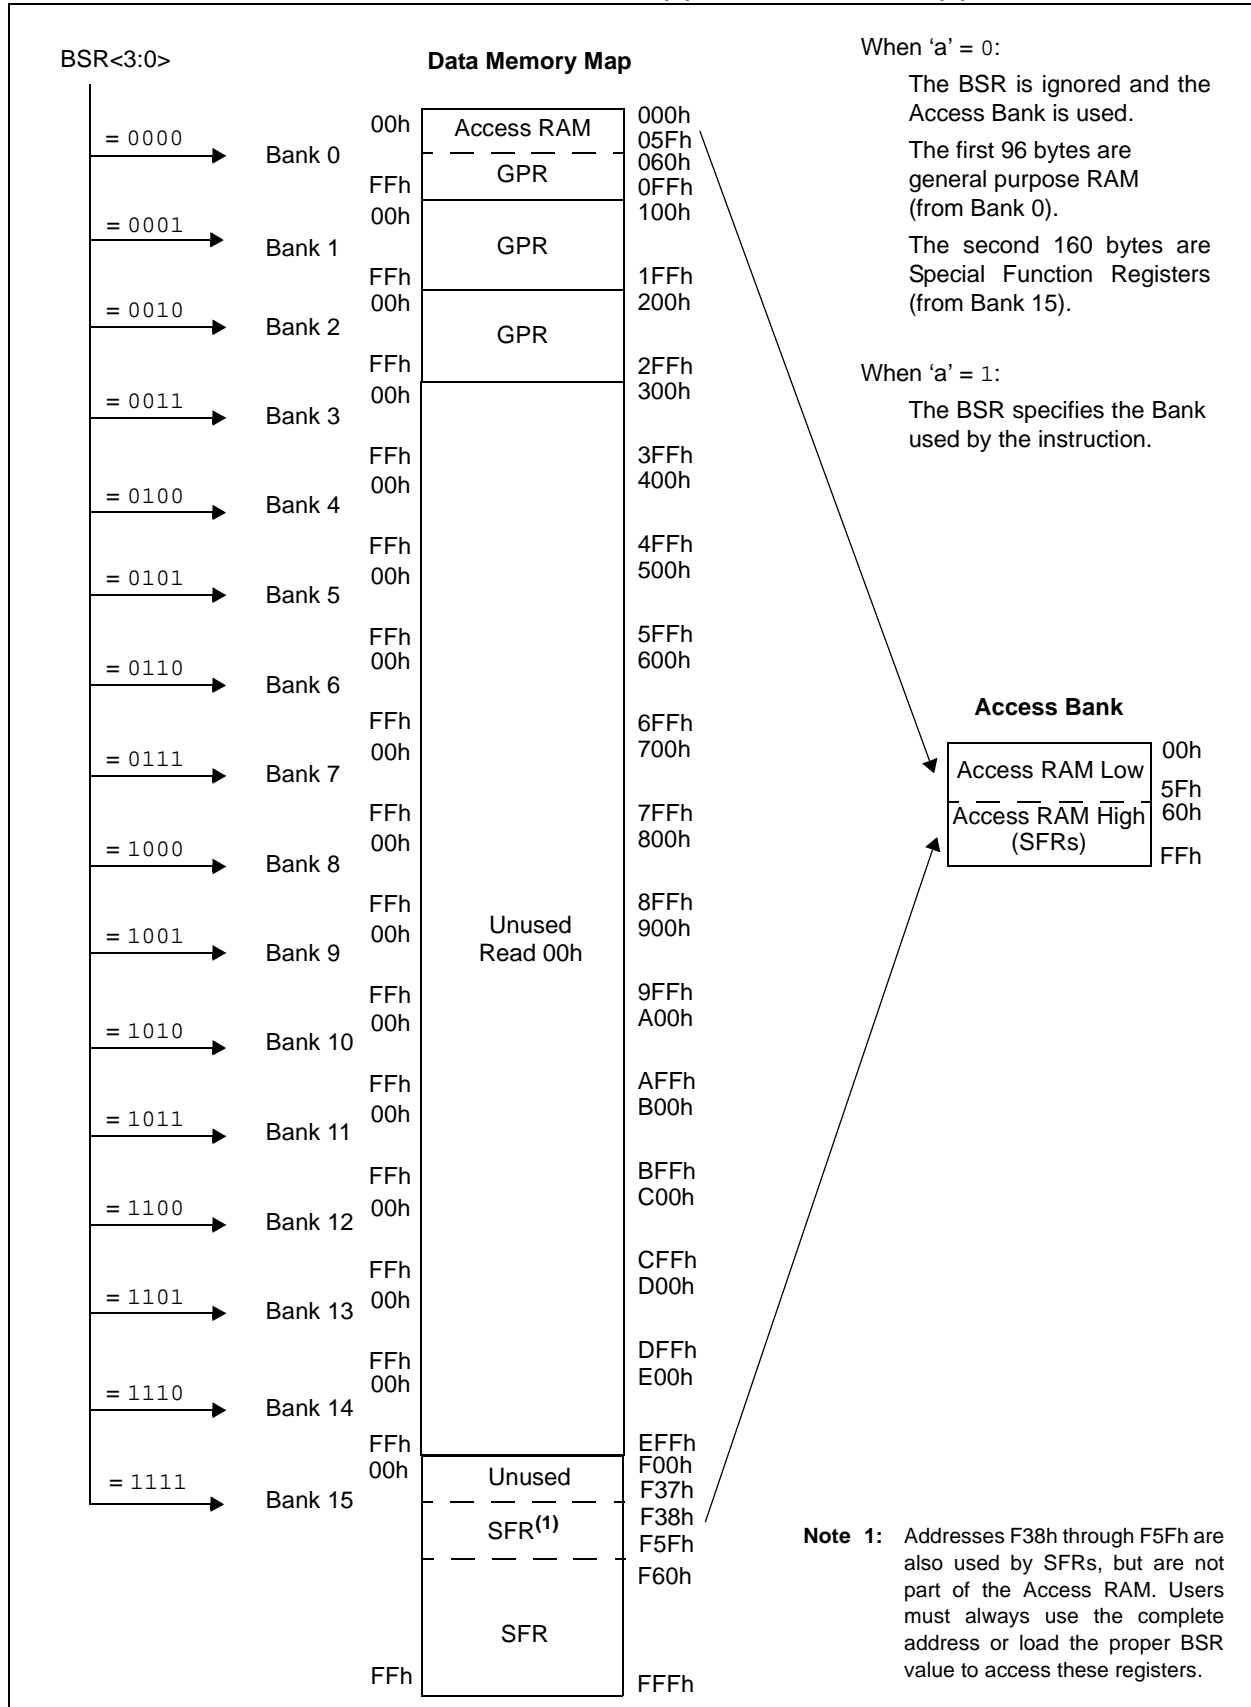

#### Details

Product Status	Active
Core Processor	PIC
Core Size	8-Bit
Speed	64MHz
Connectivity	I <sup>2</sup> C, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, HLVD, POR, PWM, WDT
Number of I/O	24
Program Memory Size	16KB (8K x 16)
Program Memory Type	FLASH
EEPROM Size	256 x 8
RAM Size	768 x 8
Voltage - Supply (Vcc/Vdd)	2.3V ~ 5.5V
Data Converters	A/D 19x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	28-SSOP (0.209", 5.30mm Width)
Supplier Device Package	28-SSOP
Purchase URL	<a href="https://www.e-xfl.com/product-detail/microchip-technology/pic18f24k22t-i-ss">https://www.e-xfl.com/product-detail/microchip-technology/pic18f24k22t-i-ss</a>

## 5.6.3.1 FSR Registers and the INDF Operand

At the core of indirect addressing are three sets of registers: FSR0, FSR1 and FSR2. Each represents a pair of 8-bit registers, FSRnH and FSRnL. Each FSR pair holds a 12-bit value, therefore, the four upper bits of the FSRnH register are not used. The 12-bit FSR value can address the entire range of the data memory in a linear fashion. The FSR register pairs, then, serve as pointers to data memory locations.

Indirect addressing is accomplished with a set of Indirect File Operands, INDF0 through INDF2. These can be thought of as “virtual” registers: they are mapped in the SFR space but are not physically implemented. Reading or writing to a particular INDF register actually accesses its corresponding FSR register pair. A read from INDF1, for example, reads the data at the address indicated by FSR1H:FSR1L. Instructions that use the INDF registers as operands actually use the contents of their corresponding FSR as a pointer to the instruction’s target. The INDF operand is just a convenient way of using the pointer.

Because indirect addressing uses a full 12-bit address, data RAM banking is not necessary. Thus, the current contents of the BSR and the Access RAM bit have no effect on determining the target address.

## 5.6.3.2 FSR Registers and POSTINC, POSTDEC, PREINC and PLUSW

In addition to the INDF operand, each FSR register pair also has four additional indirect operands. Like INDF, these are “virtual” registers which cannot be directly read or written. Accessing these registers actually accesses the location to which the associated FSR register pair points, and also performs a specific action on the FSR value. They are:

- **POSTDEC**: accesses the location to which the FSR points, then automatically decrements the FSR by 1 afterwards
- **POSTINC**: accesses the location to which the FSR points, then automatically increments the FSR by 1 afterwards
- **PREINC**: automatically increments the FSR by one, then uses the location to which the FSR points in the operation
- **PLUSW**: adds the signed value of the W register (range of -127 to 128) to that of the FSR and uses the location to which the result points in the operation.

In this context, accessing an INDF register uses the value in the associated FSR register without changing it. Similarly, accessing a PLUSW register gives the FSR value an offset by that in the W register; however, neither W nor the FSR is actually changed in the operation. Accessing the other virtual registers changes the value of the FSR register.

**FIGURE 5-10: INDIRECT ADDRESSING**

## 6.3.1 TABLAT – TABLE LATCH REGISTER

The Table Latch (TABLAT) is an 8-bit register mapped into the SFR space. The Table Latch register is used to hold 8-bit data during data transfers between program memory and data RAM.

## 6.3.2 TBLPTR – TABLE POINTER REGISTER

The Table Pointer (TBLPTR) register addresses a byte within the program memory. The TBLPTR is comprised of three SFR registers: Table Pointer Upper Byte, Table Pointer High Byte and Table Pointer Low Byte (TBLPTRU:TBLPTRH:TBLPTRL). These three registers join to form a 22-bit wide pointer. The low-order 21 bits allow the device to address up to 2 Mbytes of program memory space. The 22nd bit allows access to the device ID, the user ID and the Configuration bits.

The Table Pointer register, TBLPTR, is used by the TBLRD and TBLWT instructions. These instructions can update the TBLPTR in one of four ways based on the table operation. These operations on the TBLPTR affect only the low-order 21 bits.

## 6.3.3 TABLE POINTER BOUNDARIES

TBLPTR is used in reads, writes and erases of the Flash program memory.

When a TBLRD is executed, all 22 bits of the TBLPTR determine which byte is read from program memory directly into the TABLAT register.

When a TBLWT is executed the byte in the TABLAT register is written, not to Flash memory but, to a holding register in preparation for a program memory write. The holding registers constitute a write block which varies depending on the device (see Table 6-1). The 3, 4, or 5 LSBs of the TBLPTRL register determine which specific address within the holding register block is written to. The MSBs of the Table Pointer have no effect during TBLWT operations.

When a program memory write is executed the entire holding register block is written to the Flash memory at the address determined by the MSBs of the TBLPTR. The 3, 4, or 5 LSBs are ignored during Flash memory writes. For more detail, see **Section 6.6 “Writing to Flash Program Memory”**.

When an erase of program memory is executed, the 16 MSBs of the Table Pointer register (TBLPTR<21:6>) point to the 64-byte block that will be erased. The Least Significant bits (TBLPTR<5:0>) are ignored.

Figure 6-3 describes the relevant boundaries of TBLPTR based on Flash program memory operations.

**TABLE 6-1: TABLE POINTER OPERATIONS WITH TBLRD AND TBLWT INSTRUCTIONS**

Example	Operation on Table Pointer
TBLRD* TBLWT*	TBLPTR is not modified
TBLRD*+ TBLWT*+	TBLPTR is incremented after the read/write
TBLRD*- TBLWT*-	TBLPTR is decremented after the read/write
TBLRD+* TBLWT+*	TBLPTR is incremented before the read/write

                                  0 = Low priority

## 10.0 I/O PORTS

Depending on the device selected and features enabled, there are up to five ports available. All pins of the I/O ports are multiplexed with one or more alternate functions from the peripheral features on the device. In general, when a peripheral is enabled, that pin may not be used as a general purpose I/O pin.

Each port has five registers for its operation. These registers are:

- TRIS register (data direction register)
- PORT register (reads the levels on the pins of the device)
- LAT register (output latch)
- ANSEL register (analog input control)
- SLRCON register (port slew rate control)

The Data Latch (LAT register) is useful for read-modify-write operations on the value that the I/O pins are driving.

A simplified model of a generic I/O port, without the interfaces to other peripherals, is shown in Figure 10-1.

**FIGURE 10-1: GENERIC I/O PORT OPERATION**

## 10.1 PORTA Registers

PORTA is an 8-bit wide, bidirectional port. The corresponding data direction register is TRISA. Setting a TRISA bit (= 1) will make the corresponding PORTA pin an input (i.e., disable the output driver). Clearing a TRISA bit (= 0) will make the corresponding PORTA pin an output (i.e., enable the output driver and put the contents of the output latch on the selected pin).

Reading the PORTA register reads the status of the pins, whereas writing to it, will write to the PORT latch.

The Data Latch (LATA) register is also memory mapped. Read-modify-write operations on the LATA register read and write the latched output value for PORTA.

The RA4 pin is multiplexed with the Timer0 module clock input and one of the comparator outputs to become the RA4/T0CKI/C1OUT pin. Pins RA6 and RA7 are multiplexed with the main oscillator pins; they are enabled as oscillator or I/O pins by the selection of the main oscillator in the Configuration register (see **Section 24.1 "Configuration Bits"** for details). When they are not used as port pins, RA6 and RA7 and their associated TRIS and LAT bits are read as '0'.

The other PORTA pins are multiplexed with analog inputs, the analog VREF+ and VREF- inputs, and the comparator voltage reference output. The operation of pins RA<3:0> and RA5 as analog is selected by setting the ANSELA<5, 3:0> bits in the ANSELA register which is the default setting after a Power-on Reset.

Pins RA0 through RA5 may also be used as comparator inputs or outputs by setting the appropriate bits in the CM1CON0 and CM2CON0 registers.

**Note:** On a Power-on Reset, RA5 and RA<3:0> are configured as analog inputs and read as '0'. RA4 is configured as a digital input.

The RA4/T0CKI/C1OUT pin is a Schmitt Trigger input. All other PORTA pins have TTL input levels and full CMOS output drivers.

The TRISA register controls the drivers of the PORTA pins, even when they are being used as analog inputs. The user should ensure the bits in the TRISA register are maintained set when using them as analog inputs.

### EXAMPLE 10-1: INITIALIZING PORTA

```
MOVLB  0xF      ; Set BSR for banked SFRs
CLRF   PORTA    ; Initialize PORTA by
                  ; clearing output
                  ; data latches
CLRF   LATA      ; Alternate method

## 12.13 Register Definitions: Timer1/3/5 Control

### REGISTER 12-1: TXCON: TIMER1/3/5 CONTROL REGISTER

R/W-0/u	R/W-0/u	R/W-0/u	R/W-0/u	R/W-0/u	R/W-0/u	R/W-0/0	R/W-0/u
TMRxCS<1:0>		TxCKPS<1:0>		TxSOSCEN	TxSYNC	TxRD16	TMRxON
bit 7							bit 0

#### Legend:

R = Readable bit	W = Writable bit	U = Unimplemented bit, read as '0'
u = Bit is unchanged	x = Bit is unknown	-n/n = Value at POR and BOR/Value at all other Resets
'1' = Bit is set	'0' = Bit is cleared	

bit 7-6 **TMRxCS<1:0>**: Timer1/3/5 Clock Source Select bits

11 = Reserved. Do not use.

10 = Timer1/3/5 clock source is pin or oscillator:

If TxSOSCEN = 0:

External clock from TxCKI pin (on the rising edge)

If TxSOSCEN = 1:

Crystal oscillator on SOSC1/SOSCO pins

01 = Timer1/3/5 clock source is system clock (Fosc)

00 = Timer1/3/5 clock source is instruction clock (Fosc/4)

bit 5-4 **TxCKPS<1:0>**: Timer1/3/5 Input Clock Prescale Select bits

11 = 1:8 Prescale value

10 = 1:4 Prescale value

01 = 1:2 Prescale value

00 = 1:1 Prescale value

bit 3 **TxSOSCEN**: Secondary Oscillator Enable Control bit

1 = Dedicated Secondary oscillator circuit enabled

0 = Dedicated Secondary oscillator circuit disabled

bit 2 **TxSYNC**: Timer1/3/5 External Clock Input Synchronization Control bit

TMRxCS<1:0> = 1X

1 = Do not synchronize external clock input

0 = Synchronize external clock input with system clock (Fosc)

TMRxCS<1:0> = 0X

This bit is ignored. Timer1/3/5 uses the internal clock when TMRxCS<1:0> = 1X.

bit 1 **TxRD16**: 16-Bit Read/Write Mode Enable bit

1 = Enables register read/write of Timer1/3/5 in one 16-bit operation

0 = Enables register read/write of Timer1/3/5 in two 8-bit operation

bit 0 **TMRxON**: Timer1/3/5 On bit

1 = Enables Timer1/3/5

0 = Stops Timer1/3/5

Clears Timer1/3/5 Gate flip-flop

## 14.4.1 HALF-BRIDGE MODE

In Half-Bridge mode, two pins are used as outputs to drive push-pull loads. The PWM output signal is output on the CCPx/PxA pin, while the complementary PWM output signal is output on the PxB pin (see Figure 14-9). This mode can be used for half-bridge applications, as shown in Figure 14-9, or for full-bridge applications, where four power switches are being modulated with two PWM signals.

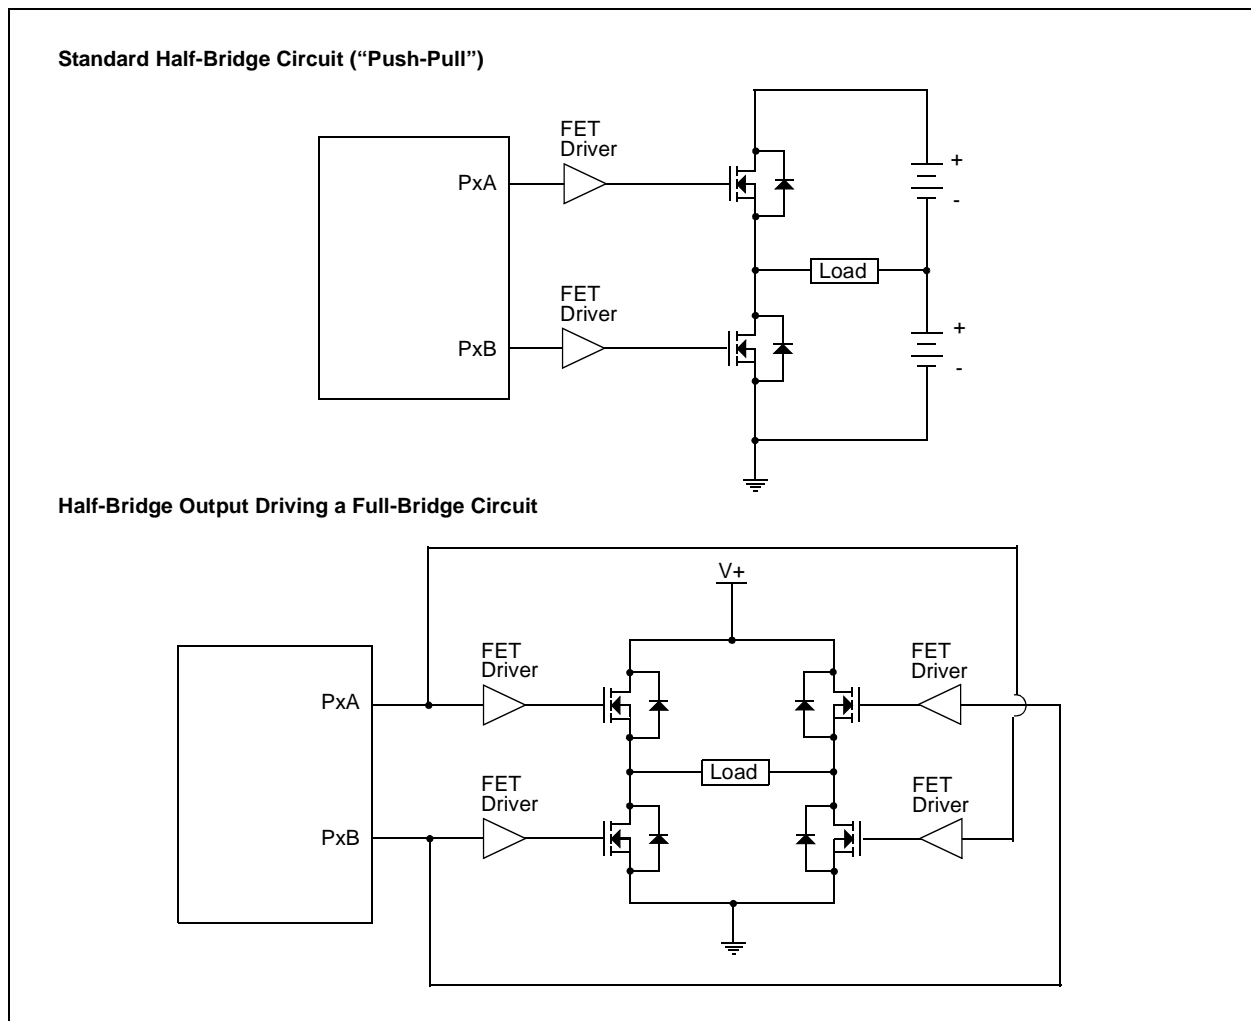

In Half-Bridge mode, the programmable dead-band delay can be used to prevent shoot-through current in half-bridge power devices. The value of the PDC<6:0> bits of the PWMxCON register sets the number of instruction cycles before the output is driven active. If the value is greater than the duty cycle, the corresponding output remains inactive during the entire cycle. See **Section 14.4.5 “Programmable Dead-Band Delay Mode”** for more details of the dead-band delay operations.

Since the PxA and PxB outputs are multiplexed with the PORT data latches, the associated TRIS bits must be cleared to configure PxA and PxB as outputs.

**FIGURE 14-8: EXAMPLE OF HALF-BRIDGE PWM OUTPUT**

**FIGURE 14-9: EXAMPLE OF HALF-BRIDGE APPLICATIONS**

## 18.4 Comparator Interrupt Operation

The comparator interrupt flag will be set whenever there is a change in the output value of the comparator. Changes are recognized by means of a mismatch circuit which consists of two latches and an exclusive-or gate (see Figure 18-2). The first latch is updated with the comparator output value, when the CMxCON0 register is read or written. The value is latched on the third cycle of the system clock, also known as Q3. This first latch retains the comparator value until another read or write of the CMxCON0 register occurs or a Reset takes place. The second latch is updated with the comparator output value on every first cycle of the system clock, also known as Q1. When the output value of the comparator changes, the second latch is updated and the output values of both latches no longer match one another, resulting in a mismatch condition. The latch outputs are fed directly into the inputs of an exclusive-or gate. This mismatch condition is detected by the exclusive-or gate and sent to the interrupt circuitry. The mismatch condition will persist until the first latch value is updated by performing a read of the CMxCON0 register or the comparator output returns to the previous state.

**Note 1:** A write operation to the CMxCON0 register will also clear the mismatch condition because all writes include a read operation at the beginning of the write cycle.

**2:** Comparator interrupts will operate correctly regardless of the state of CxOE.

When the mismatch condition occurs, the comparator interrupt flag is set. The interrupt flag is triggered by the edge of the changing value coming from the exclusive-or gate. This means that the interrupt flag can be reset once it is triggered without the additional step of reading or writing the CMxCON0 register to clear the mismatch latches. When the mismatch registers are cleared, an interrupt will occur upon the comparator's return to the previous state, otherwise no interrupt will be generated.

Software will need to maintain information about the status of the comparator output, as read from the CMxCON0 register, or CM2CON1 register, to determine the actual change that has occurred. See Figures 18-3 and 18-4.

The CxIF bit of the PIR2 register is the comparator interrupt flag. This bit must be reset by software by clearing it to '0'. Since it is also possible to write a '1' to this register, an interrupt can be generated.

In mid-range Compatibility mode the CxIE bit of the PIE2 register and the PEIE/GIEL and GIE/GIEH bits of the INTCON register must all be set to enable comparator interrupts. If any of these bits are cleared, the interrupt is not enabled, although the CxIF bit of the PIR2 register will still be set if an interrupt condition occurs.

### 18.4.1 PRESETTING THE MISMATCH LATCHES

The comparator mismatch latches can be preset to the desired state before the comparators are enabled. When the comparator is off the CxPOL bit controls the CxOUT level. Set the CxPOL bit to the desired CxOUT non-interrupt level while the CxON bit is cleared. Then, configure the desired CxPOL level in the same instruction that the CxON bit is set. Since all register writes are performed as a read-modify-write, the mismatch latches will be cleared during the instruction read phase and the actual configuration of the CxON and CxPOL bits will be clear in the final write phase.

**FIGURE 18-3: COMPARATOR INTERRUPT TIMING W/O CMxCON0 READ**

**FIGURE 18-4: COMPARATOR INTERRUPT TIMING WITH CMxCON0 READ**

**Note 1:** If a change in the CMxCON0 register (CxOUT) should occur when a read operation is being executed (start of the Q2 cycle), then the CxIF interrupt flag of the PIR2 register may not get set.

**2:** When either comparator is first enabled, bias circuitry in the comparator module may cause an invalid output from the comparator until the bias circuitry is stable. Allow about 1  $\mu$ s for bias settling then clear the mismatch condition and interrupt flags before enabling comparator interrupts.

## 21.3 Register Definitions: FVR Control

**REGISTER 21-1: VREFCON0: FIXED VOLTAGE REFERENCE CONTROL REGISTER**

R/W-0	R/W-0	R/W-0	R/W-1	U-0	U-0	U-0	U-0
FVREN	FVRST	FVRS<1:0>	—	—	—	—	—
bit 7							bit 0

**Legend:**

R = Readable bit

W = Writable bit

U = Unimplemented bit, read as '0'

u = Bit is unchanged

x = Bit is unknown

-n/n = Value at POR and BOR/Value at all other Resets

'1' = Bit is set

'0' = Bit is cleared

- bit 7      **FVREN:** Fixed Voltage Reference Enable bit  
0 = Fixed Voltage Reference is disabled  
1 = Fixed Voltage Reference is enabled
- bit 6      **FVRST:** Fixed Voltage Reference Ready Flag bit  
0 = Fixed Voltage Reference output is not ready or not enabled  
1 = Fixed Voltage Reference output is ready for use
- bit 5-4    **FVRS<1:0>:** Fixed Voltage Reference Selection bits  
00 = Fixed Voltage Reference Peripheral output is off  
01 = Fixed Voltage Reference Peripheral output is 1x (1.024V)  
10 = Fixed Voltage Reference Peripheral output is 2x (2.048V)<sup>(1)</sup>  
11 = Fixed Voltage Reference Peripheral output is 4x (4.096V)<sup>(1)</sup>
- bit 3-2    **Reserved:** Read as '0'. Maintain these bits clear.
- bit 1-0    **Unimplemented:** Read as '0'.

**Note 1:** Fixed Voltage Reference output cannot exceed V<sub>DD</sub>.

**TABLE 21-1: SUMMARY OF REGISTERS ASSOCIATED WITH FIXED VOLTAGE REFERENCE**

Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Register on Page
VREFCON0	FVREN	FVRST	FVRS<1:0>	—	—	—	—	—	332

**Legend:** — = unimplemented locations, read as '0'. Shaded bits are not used by the FVR module.

<b>GOTO</b>	<b>Unconditional Branch</b>
Syntax:	GOTO k
Operands:	$0 \leq k \leq 1048575$
Operation:	$k \rightarrow PC<20:1>$
Status Affected:	None
Encoding:	
1st word (k<7:0>)	1110 1111 k <sub>7</sub> kkk kkkk <sub>0</sub>
2nd word(k<19:8>)	1111 k <sub>19</sub> kkk kkkk kkkk <sub>8</sub>
Description:	GOTO allows an unconditional branch anywhere within entire 2-Mbyte memory range. The 20-bit value 'k' is loaded into PC<20:1>. GOTO is always a 2-cycle instruction.
Words:	2
Cycles:	2
Q Cycle Activity:	

Q1	Q2	Q3	Q4
Decode	Read literal 'k'<7:0>,	No operation	Read literal 'k'<19:8>, Write to PC
No operation	No operation	No operation	No operation

**Example:** GOTO THERE  
 After Instruction  
 PC = Address (THERE)

<b>INCF</b>	<b>Increment f</b>
Syntax:	INCF f {,d {,a}}
Operands:	$0 \leq f \leq 255$ $d \in [0,1]$ $a \in [0,1]$
Operation:	$(f) + 1 \rightarrow \text{dest}$
Status Affected:	C, DC, N, OV, Z
Encoding:	0010 10da ffff ffff
Description:	The contents of register 'f' are incremented. If 'd' is '0', the result is placed in W. If 'd' is '1', the result is placed back in register 'f' (default). If 'a' is '0', the Access Bank is selected. If 'a' is '1', the BSR is used to select the GPR bank. If 'a' is '0' and the extended instruction set is enabled, this instruction operates in Indexed Literal Offset Addressing mode whenever $f \leq 95$ (5Fh). See <b>Section 25.2.3 "Byte-Oriented and Bit-Oriented Instructions in Indexed Literal Offset Mode"</b> for details.
Words:	1
Cycles:	1
Q Cycle Activity:	

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

**Example:** INCF CNT, 1, 0

Before Instruction  
 CNT = FFh  
 Z = 0  
 C = ?  
 DC = ?  
 After Instruction  
 CNT = 00h  
 Z = 1  
 C = 1  
 DC = 1

## 25.2.3 BYTE-ORIENTED AND BIT-ORIENTED INSTRUCTIONS IN INDEXED LITERAL OFFSET MODE

**Note:** Enabling the PIC18 instruction set extension may cause legacy applications to behave erratically or fail entirely.

In addition to eight new commands in the extended set, enabling the extended instruction set also enables Indexed Literal Offset Addressing mode (**Section 5.7.1 “Indexed Addressing with Literal Offset”**). This has a significant impact on the way that many commands of the standard PIC18 instruction set are interpreted.

When the extended set is disabled, addresses embedded in opcodes are treated as literal memory locations: either as a location in the Access Bank ('a' = 0), or in a GPR bank designated by the BSR ('a' = 1). When the extended instruction set is enabled and 'a' = 0, however, a file register argument of 5Fh or less is interpreted as an offset from the pointer value in FSR2 and not as a literal address. For practical purposes, this means that all instructions that use the Access RAM bit as an argument – that is, all byte-oriented and bit-oriented instructions, or almost half of the core PIC18 instructions – may behave differently when the extended instruction set is enabled.

When the content of FSR2 is 00h, the boundaries of the Access RAM are essentially remapped to their original values. This may be useful in creating backward compatible code. If this technique is used, it may be necessary to save the value of FSR2 and restore it when moving back and forth between C and assembly routines in order to preserve the Stack Pointer. Users must also keep in mind the syntax requirements of the extended instruction set (see **Section 25.2.3.1 “Extended Instruction Syntax with Standard PIC18 Commands”**).

Although the Indexed Literal Offset Addressing mode can be very useful for dynamic stack and pointer manipulation, it can also be very annoying if a simple arithmetic operation is carried out on the wrong register. Users who are accustomed to the PIC18 programming must keep in mind that, when the extended instruction set is enabled, register addresses of 5Fh or less are used for Indexed Literal Offset Addressing.

Representative examples of typical byte-oriented and bit-oriented instructions in the Indexed Literal Offset Addressing mode are provided on the following page to show how execution is affected. The operand conditions shown in the examples are applicable to all instructions of these types.

### 25.2.3.1 Extended Instruction Syntax with Standard PIC18 Commands

When the extended instruction set is enabled, the file register argument, 'f', in the standard byte-oriented and bit-oriented commands is replaced with the literal offset value, 'k'. As already noted, this occurs only when 'f' is less than or equal to 5Fh. When an offset value is used, it must be indicated by square brackets ("[]"). As with the extended instructions, the use of brackets indicates to the compiler that the value is to be interpreted as an index or an offset. Omitting the brackets, or using a value greater than 5Fh within brackets, will generate an error in the MPASM assembler.

If the index argument is properly bracketed for Indexed Literal Offset Addressing, the Access RAM argument is never specified; it will automatically be assumed to be '0'. This is in contrast to standard operation (extended instruction set disabled) when 'a' is set on the basis of the target address. Declaring the Access RAM bit in this mode will also generate an error in the MPASM assembler.

The destination argument, 'd', functions as before.

In the latest versions of the MPASM™ assembler, language support for the extended instruction set must be explicitly invoked. This is done with either the command line option, /y, or the PE directive in the source listing.

### 25.2.4 CONSIDERATIONS WHEN ENABLING THE EXTENDED INSTRUCTION SET

It is important to note that the extensions to the instruction set may not be beneficial to all users. In particular, users who are not writing code that uses a software stack may not benefit from using the extensions to the instruction set.

Additionally, the Indexed Literal Offset Addressing mode may create issues with legacy applications written to the PIC18 assembler. This is because instructions in the legacy code may attempt to address registers in the Access Bank below 5Fh. Since these addresses are interpreted as literal offsets to FSR2 when the instruction set extension is enabled, the application may read or write to the wrong data addresses.

When porting an application to the PIC18(L)F2X/4XK22, it is very important to consider the type of code. A large, re-entrant application that is written in 'C' and would benefit from efficient compilation will do well when using the instruction set extensions. Legacy applications that heavily use the Access Bank will most likely not benefit from using the extended instruction set.
