Understanding **Embedded - FPGAs (Field Programmable Gate Array)**

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

 A DC signal is equivalent to 100% duty cycle. For example, a signal that overshoots to 4.3 V can only be at 4.3 V for 65% over the lifetime of the device; for a device lifetime of 10 years, this amounts to 65/10ths of a year.

Table 1–2. Maximum Allowed Overshoot During Transitions over a 10-Year Time Frame for Cyclone IV Devices

Symbol	Parameter	Condition (V)	Overshoot Duration as % of High Time	Unit
V_i	AC Input Voltage	$V_i = 4.20$	100	%
		$V_i = 4.25$	98	%
		$V_i = 4.30$	65	%
		$V_i = 4.35$	43	%
		$V_i = 4.40$	29	%
		$V_i = 4.45$	20	%
		$V_i = 4.50$	13	%
		$V_i = 4.55$	9	%
		$V_i = 4.60$	6	%

Figure 1–1 shows the methodology to determine the overshoot duration. The overshoot voltage is shown in red and is present on the input pin of the Cyclone IV device at over 4.3 V but below 4.4 V. From Table 1–2, for an overshoot of 4.3 V, the percentage of high time for the overshoot can be as high as 65% over a 10-year period. Percentage of high time is calculated as $([\Delta T]/T) \times 100$. This 10-year period assumes that the device is always turned on with 100% I/O toggle rate and 50% duty cycle signal. For lower I/O toggle rates and situations in which the device is in an idle state, lifetimes are increased.

Notes to Table 1-4:

- (1) All V_{CCA} pins must be powered to 2.5 V (even when PLLs are not used) and must be powered up and powered down at the same time.
- (2) You must connect V_{CCD_PLL} to V_{CCINT} through a decoupling capacitor and ferrite bead.
- (3) Power supplies must rise monotonically.
- (4) V_{CCIO} for all I/O banks must be powered up during device operation. Configurations pins are powered up by V_{CCIO} of I/O Banks 3, 8, and 9 where I/O Banks 3 and 9 only support V_{CCIO} of 1.5, 1.8, 2.5, 3.0, and 3.3 V. For fast passive parallel (FPP) configuration mode, the V_{CCIO} level of I/O Bank 8 must be powered up to 1.5, 1.8, 2.5, 3.0, and 3.3 V.
- (5) You must set V_{CC_CLKIN} to 2.5 V if you use $CLKIN$ as a high-speed serial interface (HSSI) $refclk$ or as a $DIFFCLK$ input.
- (6) The $CLKIN$ pins in I/O Banks 3B and 8B can support single-ended I/O standard when the pins are used to clock left PLLs in non-transceiver applications.
- (7) The POR time for Standard POR ranges between 50 and 200 ms. V_{CCINT} , V_{CCA} , and V_{CCIO} of I/O Banks 3, 8, and 9 must reach the recommended operating range within 50 ms.
- (8) The POR time for Fast POR ranges between 3 and 9 ms. V_{CCINT} , V_{CCA} , and V_{CCIO} of I/O Banks 3, 8, and 9 must reach the recommended operating range within 3 ms.

DC Characteristics

This section lists the I/O leakage current, pin capacitance, on-chip termination (OCT) tolerance, and bus hold specifications for Cyclone IV devices.

Supply Current

The device supply current requirement is the minimum current drawn from the power supply pins that can be used as a reference for power size planning. Use the Excel-based early power estimator (EPE) to get the supply current estimates for your design because these currents vary greatly with the resources used. Table 1-6 lists the I/O pin leakage current for Cyclone IV devices.

Table 1-6. I/O Pin Leakage Current for Cyclone IV Devices ^{(1), (2)}

Symbol	Parameter	Conditions	Device	Min	Typ	Max	Unit
I_I	Input pin leakage current	$V_I = 0\text{ V to }V_{CCIOMAX}$	—	-10	—	10	μA
I_{OZ}	Tristated I/O pin leakage current	$V_O = 0\text{ V to }V_{CCIOMAX}$	—	-10	—	10	μA

Notes to Table 1-6:

- (1) This value is specified for normal device operation. The value varies during device power-up. This applies for all V_{CCIO} settings (3.3, 3.0, 2.5, 1.8, 1.5, and 1.2 V).
- (2) The 10 μA I/O leakage current limit is applicable when the internal clamping diode is off. A higher current can be observed when the diode is on.

Bus Hold

The bus hold retains the last valid logic state after the source driving it either enters the high impedance state or is removed. Each I/O pin has an option to enable bus hold in user mode. Bus hold is always disabled in configuration mode.

Periphery Performance

This section describes periphery performance, including high-speed I/O and external memory interface.

I/O performance supports several system interfaces, such as the high-speed I/O interface, external memory interface, and the PCI/PCI-X bus interface. I/Os using the SSTL-18 Class I termination standard can achieve up to the stated DDR2 SDRAM interfacing speeds. I/Os using general-purpose I/O standards such as 3.3-, 3.0-, 2.5-, 1.8-, or 1.5-LVTTTL/LVCMOS are capable of a typical 200 MHz interfacing frequency with a 10 pF load.

 For more information about the supported maximum clock rate, device and pin planning, IP implementation, and device termination, refer to *Section III: System Performance Specifications* of the *External Memory Interfaces Handbook*.

 Actual achievable frequency depends on design- and system-specific factors. Perform HSPICE/IBIS simulations based on your specific design and system setup to determine the maximum achievable frequency in your system.

Table 1-46. Glossary (Part 3 of 5)

Letter	Term	Definitions
R	R_L	Receiver differential input discrete resistor (external to Cyclone IV devices).
	Receiver Input Waveform	<p>Receiver input waveform for LVDS and LVPECL differential standards:</p> 
	Receiver input skew margin (RSKM)	High-speed I/O block: The total margin left after accounting for the sampling window and TCCS. $RSKM = (TUI - SW - TCCS) / 2$.
S	Single-ended voltage-referenced I/O Standard	 <p>The JEDEC standard for SSTI and HSTL I/O standards defines both the AC and DC input signal values. The AC values indicate the voltage levels at which the receiver must meet its timing specifications. The DC values indicate the voltage levels at which the final logic state of the receiver is unambiguously defined. After the receiver input crosses the AC value, the receiver changes to the new logic state. The new logic state is then maintained as long as the input stays beyond the DC threshold. This approach is intended to provide predictable receiver timing in the presence of input waveform <i>ringing</i>.</p>
	SW (Sampling Window)	High-speed I/O block: The period of time during which the data must be valid to capture it correctly. The setup and hold times determine the ideal strobe position in the sampling window.
