Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

☞ A DC signal is equivalent to 100% duty cycle. For example, a signal that overshoots to 4.3 V can only be at 4.3 V for 65% over the lifetime of the device; for a device lifetime of 10 years, this amounts to 65/10ths of a year.

Table 1–2. Maximum Allowed Overshoot During Transitions over a 10-Year Time Frame for Cyclone IV Devices

Symbol	Parameter	Condition (V)	Overshoot Duration as % of High Time	Unit
V_i	AC Input Voltage	V_I = 4.20	100	%
		V_I = 4.25	98	%
		V_I = 4.30	65	%
		V_I = 4.35	43	%
		V_I = 4.40	29	%
		V_I = 4.45	20	%
		V_I = 4.50	13	%
		V_I = 4.55	9	%
		V_I = 4.60	6	%

Figure 1–1 shows the methodology to determine the overshoot duration. The overshoot voltage is shown in red and is present on the input pin of the Cyclone IV device at over 4.3 V but below 4.4 V. From Table 1–2, for an overshoot of 4.3 V, the percentage of high time for the overshoot can be as high as 65% over a 10-year period. Percentage of high time is calculated as ([delta T]/T) × 100. This 10-year period assumes that the device is always turned on with 100% I/O toggle rate and 50% duty cycle signal. For lower I/O toggle rates and situations in which the device is in an idle state, lifetimes are increased.

OCT Specifications

Table 1–8 lists the variation of OCT without calibration across process, temperature, and voltage (PVT).

Table 1–8. Series OCT Without Calibration Specifications for Cyclone IV Devices

Description	V_{CCIO} (V)	Resistance Tolerance		Unit
		Commercial Maximum	Industrial, Extended industrial, and Automotive Maximum	
Series OCT without calibration	3.0	±30	±40	%
	2.5	±30	±40	%
	1.8	±40	±50	%
	1.5	±50	±50	%
	1.2	±50	±50	%

OCT calibration is automatically performed at device power-up for OCT-enabled I/Os.

Table 1–9 lists the OCT calibration accuracy at device power-up.

Table 1–9. Series OCT with Calibration at Device Power-Up Specifications for Cyclone IV Devices

Description	V_{CCIO} (V)	Calibration Accuracy		Unit
		Commercial Maximum	Industrial, Extended industrial, and Automotive Maximum	
Series OCT with calibration at device power-up	3.0	±10	±10	%
	2.5	±10	±10	%
	1.8	±10	±10	%
	1.5	±10	±10	%
	1.2	±10	±10	%

Example 1–1 shows how to calculate the change of 50-Ω I/O impedance from 25°C at 3.0 V to 85°C at 3.15 V.

Example 1–1. Impedance Change

$\Delta R_V = (3.15 – 3) \times 1000 \times –0.026 = –3.83$

$\Delta R_T = (85 – 25) \times 0.262 = 15.72$

Because ΔR_V is negative,

$MF_V = 1 / (3.83/100 + 1) = 0.963$

Because ΔR_T is positive,

$MF_T = 15.72/100 + 1 = 1.157$

$MF = 0.963 \times 1.157 = 1.114$

$R_{final} = 50 \times 1.114 = 55.71\ \Omega$

Pin Capacitance

Table 1–11 lists the pin capacitance for Cyclone IV devices.

Table 1–11. Pin Capacitance for Cyclone IV Devices *(1)*

Notes to Table 1–11:

(1) The pin capacitance applies to FBGA, UBGA, and MBGA packages.

(2) When you use the VREF pin as a regular input or output, you can expect a reduced performance of toggle rate and t_{CO} because of higher pin capacitance.

(3) C_{VREFTB} for the EP4CE22 device is 30 pF.

		V_{CCIO} = 1.5 V ± 5% *(4)*	8	50	112	kΩ

Notes to Table 1–12:

(1) All I/O pins have an option to enable weak pull-up except the configuration, test, and JTAG pins. The weak pull-down feature is only available for JTAG TCK.

(2) Pin pull-up resistance values may be lower if an external source drives the pin higher than V_{CCIO}.

(3) $R_{\_PU} = (V_{CCIO} – V_I)/I_{R\_PU}$

Typical condition: 25°C; $V_{CCIO} = V_{CC}$, V_I = 0 V;
Maximum condition: 100°C; $V_{CCIO} = V_{CC}$ – 5%, V_I = 0 V; in which V_I refers to the input voltage at the I/O pin.

Minimum condition: –40°C; $V_{CCIO} = V_{CC}$ + 5%, V_I = 50 mV;
Typical condition: 25°C; $V_{CCIO} = V_{CC}$, $V_I = V_{CC}$ – 5%;
Maximum condition: 100°C; $V_{CCIO} = V_{CC}$ – 5%, $V_I = V_{CC}$ – 5%; in which V_I refers to the input voltage at the I/O pin.

Periphery Performance

This section describes periphery performance, including high-speed I/O and external memory interface.

I/O performance supports several system interfaces, such as the high-speed I/O interface, external memory interface, and the PCI/PCI-X bus interface. I/Os using the SSTL-18 Class I termination standard can achieve up to the stated DDR2 SDRAM interfacing speeds. I/Os using general-purpose I/O standards such as 3.3-, 3.0-, 2.5-, 1.8-, or 1.5-LVTTL/LVCMOS are capable of a typical 200 MHz interfacing frequency with a 10 pF load.

I/O Timing

Use the following methods to determine I/O timing:

- the Excel-based I/O Timing
- the Quartus II timing analyzer

The Excel-based I/O timing provides pin timing performance for each device density and speed grade. The data is typically used prior to designing the FPGA to get a timing budget estimation as part of the link timing analysis. The Quartus II timing analyzer provides a more accurate and precise I/O timing data based on the specifics of the design after place-and-route is complete.

The Excel-based I/O Timing spreadsheet is downloadable from Cyclone IV Devices Literature website.

R	R_L	Receiver differential input discrete resistor (external to Cyclone IV devices).
	Receiver Input Waveform	Receiver input waveform for LVDS and LVPECL differential standards: **Single-Ended Waveform**  **Differential Waveform (Mathematical Function of Positive & Negative Channel)** 	Receiver input skew margin (RSKM)	High-speed I/O block: The total margin left after accounting for the sampling window and TCCS. RSKM = (TUI – SW – TCCS) / 2.
S	Single-ended voltage-referenced I/O Standard	 The JEDEC standard for SSTI and HSTL I/O standards defines both the AC and DC input signal values. The AC values indicate the voltage levels at which the receiver must meet its timing specifications. The DC values indicate the voltage levels at which the final logic state of the receiver is unambiguously defined. After the receiver input crosses the AC value, the receiver changes to the new logic state. The new logic state is then maintained as long as the input stays beyond the DC threshold. This approach is intended to provide predictable receiver timing in the presence of input waveform *ringing*.
	SW (Sampling Window)	High-speed I/O block: The period of time during which the data must be valid to capture it correctly. The setup and hold times determine the ideal strobe position in the sampling window.
