Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Cyclone IV E industrial devices I7 are offered with extended operating temperature range.

Absolute Maximum Ratings

Absolute maximum ratings define the maximum operating conditions for Cyclone IV devices. The values are based on experiments conducted with the device and theoretical modeling of breakdown and damage mechanisms. The functional operation of the device is not implied at these conditions. Table 1–1 lists the absolute maximum ratings for Cyclone IV devices.

Conditions beyond those listed in Table 1–1 cause permanent damage to the device. Additionally, device operation at the absolute maximum ratings for extended periods of time have adverse effects on the device.

Table 1–1. Absolute Maximum Ratings for Cyclone IV Devices ⁽¹⁾

Note to Table 1–1:

(1) Supply voltage specifications apply to voltage readings taken at the device pins with respect to ground, not at the power supply.

Maximum Allowed Overshoot or Undershoot Voltage

During transitions, input signals may overshoot to the voltage shown in Table 1–2 and undershoot to –2.0 V for a magnitude of currents less than 100 mA and for periods shorter than 20 ns. Table 1–2 lists the maximum allowed input overshoot voltage and the duration of the overshoot voltage as a percentage over the lifetime of the device. The maximum allowed overshoot duration is specified as a percentage of high-time over the lifetime of the device.

 A DC signal is equivalent to 100% duty cycle. For example, a signal that overshoots to 4.3 V can only be at 4.3 V for 65% over the lifetime of the device; for a device lifetime of 10 years, this amounts to 65/10ths of a year.

Table 1–2. Maximum Allowed Overshoot During Transitions over a 10-Year Time Frame for Cyclone IV Devices

Symbol	Parameter	Condition (V)	Overshoot Duration as % of High Time	Unit
V_i	AC Input Voltage	$V_i = 4.20$	100	%
		$V_i = 4.25$	98	%
		$V_i = 4.30$	65	%
		$V_i = 4.35$	43	%
		$V_i = 4.40$	29	%
		$V_i = 4.45$	20	%
		$V_i = 4.50$	13	%
		$V_i = 4.55$	9	%
		$V_i = 4.60$	6	%

Figure 1–1 shows the methodology to determine the overshoot duration. The overshoot voltage is shown in red and is present on the input pin of the Cyclone IV device at over 4.3 V but below 4.4 V. From Table 1–2, for an overshoot of 4.3 V, the percentage of high time for the overshoot can be as high as 65% over a 10-year period. Percentage of high time is calculated as $([\Delta T]/T) \times 100$. This 10-year period assumes that the device is always turned on with 100% I/O toggle rate and 50% duty cycle signal. For lower I/O toggle rates and situations in which the device is in an idle state, lifetimes are increased.

Figure 1–1. Cyclone IV Devices Overshoot Duration

The OCT resistance may vary with the variation of temperature and voltage after calibration at device power-up. Use Table 1-10 and Equation 1-1 to determine the final OCT resistance considering the variations after calibration at device power-up. Table 1-10 lists the change percentage of the OCT resistance with voltage and temperature.

Hot-Socketing

Table 1-13 lists the hot-socketing specifications for Cyclone IV devices.

Table 1-13. Hot-Socketing Specifications for Cyclone IV Devices

Symbol	Parameter	Maximum
I _{IOPIN(DC)}	DC current per I/O pin	300 μA

I _{XCVRRX(DC)}	DC current per transceiver RX pin	50 mA

Note to Table 1-13:

- (1) The I/O ramp rate is 10 ns or more. For ramp rates faster than 10 ns, |I_{IOPIN}| = C dv/dt, in which C is the I/O pin capacitance and dv/dt is the slew rate.

During hot-socketing, the I/O pin capacitance is less than 15 pF and the clock pin capacitance is less than 20 pF.

Schmitt Trigger Input

Cyclone IV devices support Schmitt trigger input on the TDI, TMS, TCK, nSTATUS, nCONFIG, nCE, CONF_DONE, and DCLK pins. A Schmitt trigger feature introduces hysteresis to the input signal for improved noise immunity, especially for signals with slow edge rate. Table 1–14 lists the hysteresis specifications across the supported V_{CCIO} range for Schmitt trigger inputs in Cyclone IV devices.

- (2) AC load $CL = 10$ pF
- (3) For more information about interfacing Cyclone IV devices with 3.3/3.0/2.5-V LVTTTL/LVCMOS I/O standards, refer to *AN 447: Interfacing Cyclone III and Cyclone IV Devices with 3.3/3.0/2.5-V LVTTTL/LVCMOS I/O Systems*.

Notes to Table 1–21:

- (1) This specification is valid for transmitter output jitter specification with a maximum total jitter value of 112 ps, typically for 3.125 Gbps SRIO and XAUI protocols.
- (2) The minimum `reconfig_clk` frequency is 2.5 MHz if the transceiver channel is configured in **Transmitter Only** mode. The minimum `reconfig_clk` frequency is 37.5 MHz if the transceiver channel is configured in **Receiver Only** or **Receiver and Transmitter** mode.
- (3) The device cannot tolerate prolonged operation at this absolute maximum.
- (4) The rate matcher supports only up to ± 300 parts per million (ppm).
- (5) Supported for the F169 and F324 device packages only.
- (6) Supported for the F484, F672, and F896 device packages only. Pending device characterization.
- (7) To support CDR ppm tolerance greater than ± 300 ppm, implement ppm detector in user logic and configure CDR to Manual Lock Mode.
- (8) Asynchronous spread-spectrum clocking is not supported.
- (9) For the EP4CGX30 (F484 package only), EP4CGX50, and EP4CGX75 devices, the CDR ppl tolerance is ± 200 ppm.
- (10) Time taken until `p11_locked` goes high after `p11_powerdown` deasserts.
- (11) Time that the CDR must be kept in lock-to-reference mode after `rx_analogreset` deasserts and before `rx_locktodata` is asserted in manual mode.
- (12) Time taken to recover valid data after the `rx_locktodata` signal is asserted in manual mode (Figure 1–2), or after `rx_freqlocked` signal goes high in automatic mode (Figure 1–3).
- (13) Time taken to recover valid data after the `rx_locktodata` signal is asserted in manual mode.
- (14) Time taken to recover valid data after the `rx_freqlocked` signal goes high in automatic mode.
- (15) To support data rates lower than the minimum specification through oversampling, use the CDR in LTR mode only.

$t_{CASC_OUTJITTER_PERIOD_DEDCLK}$ ^{(8), (9)}	Period jitter for dedicated clock output in cascaded PLLs ($F_{OUT} \geq 100$ MHz)	—	—	425	ps
	Period jitter for dedicated clock output in cascaded PLLs ($F_{OUT} < 100$ MHz)	—	—	42.5	mUI

Notes to Table 1–25:

- (1) This table is applicable for general purpose PLLs and multipurpose PLLs.
- (2) You must connect V_{CCD_PLL} to V_{CCINT} through the decoupling capacitor and ferrite bead.
- (3) This parameter is limited in the Quartus II software by the I/O maximum frequency. The maximum I/O frequency is different for each I/O standard.
- (4) The V_{CO} frequency reported by the Quartus II software in the PLL Summary section of the compilation report takes into consideration the V_{CO} post-scale counter K value. Therefore, if the counter K has a value of 2, the frequency reported can be lower than the f_{VCO} specification.
- (5) A high input jitter directly affects the PLL output jitter. To have low PLL output clock jitter, you must provide a clean clock source that is less than 200 ps.
- (6) Peak-to-peak jitter with a probability level of 10^{-12} (14 sigma, 99.9999999974404% confidence level). The output jitter specification applies to the intrinsic jitter of the PLL when an input jitter of 30 ps is applied.
- (7) With 100-MHz $scanclk$ frequency.
- (8) The cascaded PLLs specification is applicable only with the following conditions:
 - Upstream PLL— $0.59 \text{ MHz} \leq \text{Upstream PLL bandwidth} < 1 \text{ MHz}$
 - Downstream PLL—Downstream PLL bandwidth $> 2 \text{ MHz}$
- (9) PLL cascading is not supported for transceiver applications.

I/O Timing

Use the following methods to determine I/O timing:

- the Excel-based I/O Timing
- the Quartus II timing analyzer

The Excel-based I/O timing provides pin timing performance for each device density and speed grade. The data is typically used prior to designing the FPGA to get a timing budget estimation as part of the link timing analysis. The Quartus II timing analyzer provides a more accurate and precise I/O timing data based on the specifics of the design after place-and-route is complete.

The Excel-based I/O Timing spreadsheet is downloadable from Cyclone IV Devices Literature website.
