Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

 A DC signal is equivalent to 100% duty cycle. For example, a signal that overshoots to 4.3 V can only be at 4.3 V for 65% over the lifetime of the device; for a device lifetime of 10 years, this amounts to 65/10ths of a year.

Table 1–2. Maximum Allowed Overshoot During Transitions over a 10-Year Time Frame for Cyclone IV Devices

Symbol	Parameter	Condition (V)	Overshoot Duration as % of High Time	Unit
V_i	AC Input Voltage	$V_i = 4.20$	100	%
		$V_i = 4.25$	98	%
		$V_i = 4.30$	65	%
		$V_i = 4.35$	43	%
		$V_i = 4.40$	29	%
		$V_i = 4.45$	20	%
		$V_i = 4.50$	13	%
		$V_i = 4.55$	9	%
		$V_i = 4.60$	6	%

Figure 1–1 shows the methodology to determine the overshoot duration. The overshoot voltage is shown in red and is present on the input pin of the Cyclone IV device at over 4.3 V but below 4.4 V. From Table 1–2, for an overshoot of 4.3 V, the percentage of high time for the overshoot can be as high as 65% over a 10-year period. Percentage of high time is calculated as $([\Delta T]/T) \times 100$. This 10-year period assumes that the device is always turned on with 100% I/O toggle rate and 50% duty cycle signal. For lower I/O toggle rates and situations in which the device is in an idle state, lifetimes are increased.

DC Characteristics

This section lists the I/O leakage current, pin capacitance, on-chip termination (OCT) tolerance, and bus hold specifications for Cyclone IV devices.

Supply Current

The device supply current requirement is the minimum current drawn from the power supply pins that can be used as a reference for power size planning. Use the Excel-based early power estimator (EPE) to get the supply current estimates for your design because these currents vary greatly with the resources used. Table 1-6 lists the I/O pin leakage current for Cyclone IV devices.

Table 1-6. I/O Pin Leakage Current for Cyclone IV Devices ^{(1), (2)}

Symbol	Parameter	Conditions	Device	Min	Typ	Max	Unit
I_I	Input pin leakage current	$V_I = 0\text{ V to }V_{CCIO\text{MAX}}$	—	-10	—	10	μA
I_{OZ}	Tristated I/O pin leakage current	$V_O = 0\text{ V to }V_{CCIO\text{MAX}}$	—	-10	—	10	μA

Notes to Table 1-6:

- (1) This value is specified for normal device operation. The value varies during device power-up. This applies for all V_{CCIO} settings (3.3, 3.0, 2.5, 1.8, 1.5, and 1.2 V).
- (2) The 10 μA I/O leakage current limit is applicable when the internal clamping diode is off. A higher current can be observed when the diode is on.

Bus Hold

The bus hold retains the last valid logic state after the source driving it either enters the high impedance state or is removed. Each I/O pin has an option to enable bus hold in user mode. Bus hold is always disabled in configuration mode.

Table 1-7 lists bus hold specifications for Cyclone IV devices.

Notes to Table 1-25:

- (1) This table is applicable for general purpose PLLs and multipurpose PLLs.
- (2) You must connect V_{CCD_PLL} to V_{CCINT} through the decoupling capacitor and ferrite bead.
- (3) This parameter is limited in the Quartus II software by the I/O maximum frequency. The maximum I/O frequency is different for each I/O standard.
- (4) The V_{CO} frequency reported by the Quartus II software in the PLL Summary section of the compilation report takes into consideration the V_{CO} post-scale counter K value. Therefore, if the counter K has a value of 2, the frequency reported can be lower than the f_{VCO} specification.
- (5) A high input jitter directly affects the PLL output jitter. To have low PLL output clock jitter, you must provide a clean clock source that is less than 200 ps.
- (6) Peak-to-peak jitter with a probability level of 10^{-12} (14 sigma, 99.9999999974404% confidence level). The output jitter specification applies to the intrinsic jitter of the PLL when an input jitter of 30 ps is applied.
- (7) With 100-MHz $scanclk$ frequency.
- (8) The cascaded PLLs specification is applicable only with the following conditions:
 - Upstream PLL— $0.59 \text{ MHz} \leq \text{Upstream PLL bandwidth} < 1 \text{ MHz}$
 - Downstream PLL—Downstream PLL bandwidth $> 2 \text{ MHz}$
- (9) PLL cascading is not supported for transceiver applications.

 For more information about the supported maximum clock rate, device and pin planning, IP implementation, and device termination, refer to *Section III: System Performance Specifications* of the *External Memory Interfaces Handbook*.

 Actual achievable frequency depends on design- and system-specific factors. Perform HSPICE/IBIS simulations based on your specific design and system setup to determine the maximum achievable frequency in your system.

I/O Timing

Use the following methods to determine I/O timing:

- the Excel-based I/O Timing
- the Quartus II timing analyzer

The Excel-based I/O timing provides pin timing performance for each device density and speed grade. The data is typically used prior to designing the FPGA to get a timing budget estimation as part of the link timing analysis. The Quartus II timing analyzer provides a more accurate and precise I/O timing data based on the specifics of the design after place-and-route is complete.

The Excel-based I/O Timing spreadsheet is downloadable from Cyclone IV Devices Literature website.

S	Single-ended voltage-referenced I/O Standard	 <p>The JEDEC standard for SSTI and HSTL I/O standards defines both the AC and DC input signal values. The AC values indicate the voltage levels at which the receiver must meet its timing specifications. The DC values indicate the voltage levels at which the final logic state of the receiver is unambiguously defined. After the receiver input crosses the AC value, the receiver changes to the new logic state. The new logic state is then maintained as long as the input stays beyond the DC threshold. This approach is intended to provide predictable receiver timing in the presence of input waveform <i>ringing</i>.</p>
	SW (Sampling Window)	High-speed I/O block: The period of time during which the data must be valid to capture it correctly. The setup and hold times determine the ideal strobe position in the sampling window.

Letter	Term	Definitions
T	t_C	High-speed receiver and transmitter input and output clock period.
	Channel-to-channel-skew (TCCS)	High-speed I/O block: The timing difference between the fastest and slowest output edges, including t_{CO} variation and clock skew. The clock is included in the TCCS measurement.
	t_{cin}	Delay from the clock pad to the I/O input register.
	t_{CO}	Delay from the clock pad to the I/O output.
	t_{cout}	Delay from the clock pad to the I/O output register.
	t_{DUTY}	High-speed I/O block: Duty cycle on high-speed transmitter output clock.
	t_{FALL}	Signal high-to-low transition time (80–20%).
	t_H	Input register hold time.
	Timing Unit Interval (TUI)	High-speed I/O block: The timing budget allowed for skew, propagation delays, and data sampling window. (TUI = $1/(\text{Receiver Input Clock Frequency Multiplication Factor}) = t_C/w$).
	$t_{INJITTER}$	Period jitter on the PLL clock input.
	$t_{OUTJITTER_DEDCLK}$	Period jitter on the dedicated clock output driven by a PLL.
	$t_{OUTJITTER_IO}$	Period jitter on the general purpose I/O driven by a PLL.
	t_{pllcin}	Delay from the PLL inclk pad to the I/O input register.
	$t_{pllcout}$	Delay from the PLL inclk pad to the I/O output register.
	Transmitter Output Waveform	<p>Transmitter output waveforms for the LVDS, mini-LVDS, PPDS and RSDS Differential I/O Standards:</p> 
	t_{RISE}	Signal low-to-high transition time (20–80%).
