What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Reset		Nine types of reset • RES# pin reset: Generated when the RES# pin is driven low. • Power-on reset: Generated when the RES# pin is driven high and VCC = AVCC0 = AVCC1 rises. • Voltage-monitoring 0 reset: Generated when VCC = AVCC0 = AVCC1 falls. • Voltage-monitoring 1 reset: Generated when VCC = AVCC0 = AVCC1 falls. • Voltage-monitoring 2 reset: Generated when VCC = AVCC0 = AVCC1 falls. • Deep software standby reset: Generated in response to an interrupt to trigger release from deep software standby. • Independent watchdog timer reset: Generated when the independent watchdog timer underflows, or a refresh error occurs. • Watchdog timer reset: Generated when the watchdog timer underflows, or a refresh error occurs. • Software reset: Generated by register setting.
Power-on reset		If the RES# pin is at the high level when power is supplied, an internal reset is generated. After VCC = AVCC0 = AVCC1 has exceeded the voltage detection level and the specified period has elapsed, the reset is cancelled.

2.1   General-Purpose Registers (R0 to R15)

This CPU has sixteen 32-bit general-purpose registers (R0 to R15). R0 to R15 can be used as data registers or address registers.

R0, a general-purpose register, also functions as the stack pointer (SP).

The stack pointer is switched to operate as the interrupt stack pointer (ISP) or user stack pointer (USP) by the value of the stack pointer select bit (U) in the processor status word (PSW).

2.2   Control Registers

(1)   Interrupt Stack Pointer (ISP) / User Stack Pointer (USP)

The stack pointer (SP) can be either of two types, the interrupt stack pointer (ISP) or the user stack pointer (USP). Whether the stack pointer operates as the ISP or USP depends on the value of the stack pointer select bit (U) in the processor status word (PSW).

(2)   Exception Table Register (EXTB)

The exception table register (EXTB) specifies the address where the exception vector table starts.

(3)   Interrupt Table Register (INTB)

The interrupt table register (INTB) specifies the address where the interrupt vector table starts.

(4)   Program Counter (PC)

The program counter (PC) indicates the address of the instruction being executed.

(5)   Processor Status Word (PSW)

The processor status word (PSW) indicates the results of instruction execution or the state of the CPU.

(6)   Backup PC (BPC)

The backup PC (BPC) is provided to speed up response to interrupts.

After a fast interrupt has been generated, the contents of the program counter (PC) are saved in the BPC register.

(7)   Backup PSW (BPSW)

The backup PSW (BPSW) is provided to speed up response to interrupts.

After a fast interrupt has been generated, the contents of the processor status word (PSW) are saved in the BPSW. The allocation of bits in the BPSW corresponds to that in the PSW.

(8)   Fast Interrupt Vector Register (FINTV)

The fast interrupt vector register (FINTV) is provided to speed up response to interrupts.

The FINTV register specifies a branch destination address when a fast interrupt has been generated.

(9)   Floating-Point Status Word (FPSW)

The floating-point status word (FPSW) indicates the results of floating-point operations.

When an exception handling enable bit (Ej) enables the exception handling (Ej = 1), the exception cause can be identified by checking the corresponding Cj flag in the exception handling routine. If the exception handling is masked (Ej = 0), the occurrence of exception can be checked by reading the Fj flag at the end of a series of processing. Once the Fj flag has been set to 1, this value is retained until it is cleared to 0 by software (j = X, U, Z, O, or V).

LCD_CLK Output clock High pulse width	t_{LOH}	0.4	—	0.6	t_{Lcyc}	
LCD data output Delay timing	t_{DD}	−3.5[*2]	—	4[*2]	ns	Figure 5.71

Note 1.   Parallel RGB888,666,565: Max. 27 MHz
          Serial RGB888: Max. 30 MHz (4x speed)
Note 2.   We recommend using pins that have a letter ("-A", "-B", etc) to indicate group membership appended to their names as groups.
          For the GLCDC interface, the AC portion of the electrical characteristics is measured for each group.
          If we use group "-A" and "-B" combination, "LCD data output Delay timing (t_{DD})" is Min = −5.0 ns, Max = 5.5 ns.

Note: The above specification values apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the above ranges.

Note 1.   The conversion time includes the sampling time and the comparison time. As the test conditions, the number of sampling states is indicated.

Note 2.   The value in parentheses indicates the sampling time.
