

Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "<u>Embedded -</u> <u>Microcontrollers</u>"

Details

| Product Status | Active |
|----------------------------|---|
| Core Processor | 8051 |
| Core Size | 8-Bit |
| Speed | 50MHz |
| Connectivity | SMBus (2-Wire/I ² C), CANbus, SPI, UART/USART |
| Peripherals | POR, PWM, Temp Sensor, WDT |
| Number of I/O | 25 |
| Program Memory Size | 16KB (16K x 8) |
| Program Memory Type | FLASH |
| EEPROM Size | - |
| RAM Size | 2.25K x 8 |
| Voltage - Supply (Vcc/Vdd) | 1.8V ~ 5.25V |
| Data Converters | A/D 25x12b |
| Oscillator Type | Internal |
| Operating Temperature | -40°C ~ 125°C (TA) |
| Mounting Type | Surface Mount |
| Package / Case | 32-VFQFN Exposed Pad |
| Supplier Device Package | 32-QFN (5x5) |
| Purchase URL | https://www.e-xfl.com/product-detail/silicon-labs/c8051f565-imr |

6.2. Output Code Formatting

The registers ADC0H and ADC0L contain the high and low bytes of the output conversion code. When the repeat count is set to 1, conversion codes are represented in 12-bit unsigned integer format and the output conversion code is updated after each conversion. Inputs are measured from 0 to $V_{REF} \times 4095/4096$. Data can be right-justified or left-justified, depending on the setting of the AD0LJST bit (ADC0CN.2). Unused bits in the ADC0H and ADC0L registers are set to 0. Example codes are shown below for both right-justified and left-justified data.

| Input Voltage | Right-Justified ADC0H:ADC0L (AD0LJST = 0) | Left-Justified ADC0H:ADC0L (AD0LJST = 1) |
|------------------|--|---|
| VREF x 4095/4096 | 0x0FFF | 0xFFF0 |
| VREF x 2048/4096 | 0x0800 | 0x8000 |
| VREF x 2047/4096 | 0x07FF | 0x7FF0 |
| 0 | 0x0000 | 0x0000 |

When the ADC0 Repeat Count is greater than 1, the output conversion code represents the accumulated result of the conversions performed and is updated after the last conversion in the series is finished. Sets of 4, 8, or 16 consecutive samples can be accumulated and represented in unsigned integer format. The repeat count can be selected using the AD0RPT bits in the ADC0CF register. The value must be right-justified (AD0LJST = 0), and unused bits in the ADC0H and ADC0L registers are set to 0. The following example shows right-justified codes for repeat counts greater than 1. Notice that accumulating 2^n samples is equivalent to left-shifting by *n* bit positions when all samples returned from the ADC have the same value.

| Input Voltage | Repeat Count = 4 | Repeat Count = 8 | Repeat Count = 16 |
|------------------------------|------------------|------------------|-------------------|
| V _{REF} x 4095/4096 | 0x3FFC | 0x7FF8 | 0xFFF0 |
| V _{REF} x 2048/4096 | 0x2000 | 0x4000 | 0x8000 |
| V _{REF} x 2047/4096 | 0x1FFC | 0x3FF8 | 0x7FF0 |
| 0 | 0x0000 | 0x0000 | 0x0000 |

6.2.1. Settling Time Requirements

A minimum tracking time is required before an accurate conversion is performed. This tracking time is determined by any series impedance, including the AMUX0 resistance, the ADC0 sampling capacitance, and the accuracy required for the conversion.

Figure 6.5 shows the equivalent ADC0 input circuit. The required ADC0 settling time for a given settling accuracy (SA) may be approximated by Equation 6.1. When measuring the Temperature Sensor output, use the settling time specified in Table 5.10. When measuring V_{DD} with respect to GND, R_{TOTAL} reduces to R_{MUX} . See Table 5.9 for ADC0 minimum settling time requirements as well as the mux impedance and sampling capacitor values.

$$t = ln\left(\frac{2^{n}}{SA}\right) \times R_{TOTAL}C_{SAMPLE}$$

Equation 6.1. ADC0 Settling Time Requirements

Where:

SA is the settling accuracy, given as a fraction of an LSB (for example, 0.25 to settle within 1/4 LSB). *t* is the required settling time in seconds. R_{TOTAL} is the sum of the AMUX0 resistance and any external source resistance. *n* is the ADC resolution in bits (10).

8. Comparators

The C8051F55x/56x/57x devices include two on-chip programmable voltage Comparators. A block diagram of the comparators is shown in Figure 8.1, where "n" is the comparator number (0 or 1). The two Comparators operate identically except that Comparator0 can also be used a reset source. For input selection details, refer to SFR Definition 8.5 and SFR Definition 8.6.

Each Comparator offers programmable response time and hysteresis, an analog input multiplexer, and two outputs that are optionally available at the Port pins: a synchronous "latched" output (CP0, CP1), or an asynchronous "raw" output (CP0A, CP1A). The asynchronous signal is available even when the system clock is not active. This allows the Comparators to operate and generate an output with the device in STOP mode. When assigned to a Port pin, the Comparator outputs may be configured as open drain or push-pull (see Section "19.4. Port I/O Initialization" on page 174). Comparator0 may also be used as a reset source (see Section "16.5. Comparator0 Reset" on page 142).

The Comparator0 inputs are selected in the CPT0MX register (SFR Definition 8.5). The CMX0P1-CMX0P0 bits select the Comparator0 positive input; the CMX0N1-CMX0N0 bits select the Comparator0 negative input. The Comparator1 inputs are selected in the CPT1MX register (SFR Definition 8.6). The CMX1P1-CMX1P0 bits select the Comparator1 positive input; the CMX1N1-CMX1N0 bits select the Comparator1 negative input.

Important Note About Comparator Inputs: The Port pins selected as Comparator inputs should be configured as analog inputs in their associated Port configuration register, and configured to be skipped by the Crossbar (for details on Port configuration, see Section "19.1. Port I/O Modes of Operation" on page 170).

Figure 8.1. Comparator Functional Block Diagram

10. CIP-51 Microcontroller

The MCU system controller core is the CIP-51 microcontroller. The CIP-51 is fully compatible with the MCS-51[™] instruction set; standard 803x/805x assemblers and compilers can be used to develop software. The MCU family has a superset of all the peripherals included with a standard 8051. The CIP-51 also includes on-chip debug hardware (see description in Section 27), and interfaces directly with the analog and digital subsystems providing a complete data acquisition or control-system solution in a single integrated circuit.

The CIP-51 Microcontroller core implements the standard 8051 organization and peripherals as well as additional custom peripherals and functions to extend its capability (see Figure 10.1 for a block diagram). The CIP-51 includes the following features:

- Fully Compatible with MCS-51 Instruction Set
- 50 MIPS Peak Throughput with 50 MHz Clock
- 0 to 50 MHz Clock Frequency
- Extended Interrupt Handler
- Reset Input
- Power Management Modes
- On-chip Debug Logic
- Program and Data Memory Security

10.1. Performance

The CIP-51 employs a pipelined architecture that greatly increases its instruction throughput over the standard 8051 architecture. In a standard 8051, all instructions except for MUL and DIV take 12 or 24 system clock cycles to execute, and usually have a maximum system clock of 12 MHz. By contrast, the CIP-51 core executes 70% of its instructions in one or two system clock cycles, with no instructions taking more than eight system clock cycles.

Notes on Registers, Operands and Addressing Modes:

Rn—Register R0–R7 of the currently selected register bank.

@Ri—Data RAM location addressed indirectly through R0 or R1.

rel—8-bit, signed (two's complement) offset relative to the first byte of the following instruction. Used by SJMP and all conditional jumps.

direct—8-bit internal data location's address. This could be a direct-access Data RAM location (0x00–0x7F) or an SFR (0x80–0xFF).

#data—8-bit constant

#data16—16-bit constant

bit—Direct-accessed bit in Data RAM or SFR

addr11—11-bit destination address used by ACALL and AJMP. The destination must be within the same 2 kB page of program memory as the first byte of the following instruction.

addr16—16-bit destination address used by LCALL and LJMP. The destination may be anywhere within the 64 kB program memory space.

There is one unused opcode (0xA5) that performs the same function as NOP. All mnemonics copyrighted © Intel Corporation 1980.

10.3. CIP-51 Register Descriptions

Following are descriptions of SFRs related to the operation of the CIP-51 System Controller. Reserved bits should not be set to logic I. Future product versions may use these bits to implement new features in which case the reset value of the bit will be logic 0, selecting the feature's default state. Detailed descriptions of the remaining SFRs are included in the sections of the datasheet associated with their corresponding system function.

SFR Definition 10.3. SP: Stack Pointer

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--|---------|---|---|---|---|---|---|---|
| Name | SP[7:0] | | | | | | | |
| Туре | R/W | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 |

| Bit | Name | Function |
|-----|---------|--|
| 7:0 | SP[7:0] | Stack Pointer. |
| | | The Stack Pointer holds the location of the top of the stack. The stack pointer is incre- mented before every PUSH operation. The SP register defaults to 0x07 after reset. |

SFR Definition 10.4. ACC: Accumulator

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|-------------|-------------|---------------|--------------|-------------|---|---|---|
| Name | | | | ACC | [7:0] | | | |
| Туре | R/W | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| SFR Ad | dress = 0xE | 0; SFR Page | e = All Pages | ; Bit-Addres | sable | | | |
| | | | | | – /· | | | |

| Bit | Name | Function |
|-----|----------|---|
| 7:0 | ACC[7:0] | Accumulator. |
| | | This register is the accumulator for arithmetic operations. |

SFR Definition 10.5. B: B Register

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|--------|---|---|---|---|---|---|---|
| Name | B[7:0] | | | | | | | |
| Туре | R/W | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

SFR Address = 0xF0; SFR Page = All Pages; Bit-Addressable

| Bit | Name | Function |
|-----|--------|---|
| 7:0 | B[7:0] | B Register. |
| | | This register serves as a second accumulator for certain arithmetic operations. |

C8051F55x/56x/57x.

11.2.1.1. General Purpose Registers

The lower 32 bytes of data memory, locations 0x00 through 0x1F, may be addressed as four banks of general-purpose registers. Each bank consists of eight byte-wide registers designated R0 through R7. Only one of these banks may be enabled at a time. Two bits in the program status word, RS0 (PSW.3) and RS1 (PSW.4), select the active register bank (see description of the PSW in SFR Definition 10.6). This allows fast context switching when entering subroutines and interrupt service routines. Indirect addressing modes use registers R0 and R1 as index registers.

11.2.1.2. Bit Addressable Locations

In addition to direct access to data memory organized as bytes, the sixteen data memory locations at 0x20 through 0x2F are also accessible as 128 individually addressable bits. Each bit has a bit address from 0x00 to 0x7F. Bit 0 of the byte at 0x20 has bit address 0x00 while bit7 of the byte at 0x20 has bit address 0x07. Bit 7 of the byte at 0x2F has bit address 0x7F. A bit access is distinguished from a full byte access by the type of instruction used (bit source or destination operands as opposed to a byte source or destination).

The MCS-51[™] assembly language allows an alternate notation for bit addressing of the form XX.B where XX is the byte address and B is the bit position within the byte. For example, the instruction:

MOV C, 22.3h

moves the Boolean value at 0x13 (bit 3 of the byte at location 0x22) into the Carry flag.

11.2.1.3. Stack

A programmer's stack can be located anywhere in the 256-byte data memory. The stack area is designated using the Stack Pointer (SP) SFR. The SP will point to the last location used. The next value pushed on the stack is placed at SP+1 and then SP is incremented. A reset initializes the stack pointer to location 0x07. Therefore, the first value pushed on the stack is placed at location 0x08, which is also the first register (R0) of register bank 1. Thus, if more than one register bank is to be used, the SP should be initialized to a location in the data memory not being used for data storage. The stack depth can extend up to 256 bytes.

12.3. SFR Page Stack Example

The following is an example that shows the operation of the SFR Page Stack during interrupts. In this example, the SFR Control register is left in the default enabled state (i.e., SFRPGEN = 1), and the CIP-51 is executing in-line code that is writing values to SPI Data Register (SFR "SPI0DAT", located at address 0xA3 on SFR Page 0x00). The device is also using the CAN peripheral (CAN0) and the Programmable Counter Array (PCA0) peripheral to generate a PWM output. The PCA is timing a critical control function in its interrupt service and so its associated ISR that is set to high priority. At this point, the SFR page is set to access the SPI0DAT SFR (SFRPAGE = 0x00). See Figure 12.2.

Figure 12.2. SFR Page Stack While Using SFR Page 0x0 To Access SPI0DAT

SFR Definition 12.4. SFRLAST: SFR Last

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|---|--------------|---|---|---|---|---|---|
| Name | | SFRLAST[7:0] | | | | | | |
| Туре | | R/W | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

SFR Address = 0xA7; SFR Page = All Pages

| Bit | Name | Function |
|-----|--------------|---|
| 7:0 | SFRLAST[7:0] | SFR Page Stack Bits. |
| | | This is the value that will go to the SFRNEXT register upon a return from inter- rupt. |
| | | Write: Sets the SFR Page in the last entry of the SFR Stack. This will cause the SFRNEXT SFR to have this SFR page value upon a return from interrupt. |
| | | Read: Returns the value of the SFR page contained in the last entry of the SFR stack. |
| | | SFR page context is retained upon interrupts/return from interrupts in a 3 byte SFR Page Stack: SFRPAGE is the first entry, SFRNEXT is the second, and SFRLAST is the third entry. The SFR stack bytes may be used alter the context in the SFR Page Stack, and will not cause the stack to "push" or "pop". Only interrupts and return from interrupts cause pushes and pops of the SFR Page Stack. |

14.2. Non-volatile Data Storage

The Flash memory can be used for non-volatile data storage as well as program code. This allows data such as calibration coefficients to be calculated and stored at run time. Data is written using the MOVX write instruction and read using the MOVC instruction. Note: MOVX read instructions always target XRAM.

14.3. Security Options

The CIP-51 provides security options to protect the Flash memory from inadvertent modification by software as well as to prevent the viewing of proprietary program code and constants. The Program Store Write Enable (bit PSWE in register PSCTL) and the Program Store Erase Enable (bit PSEE in register PSCTL) bits protect the Flash memory from accidental modification by software. PSWE must be explicitly set to 1 before software can modify the Flash memory; both PSWE and PSEE must be set to 1 before software can erase Flash memory. Additional security features prevent proprietary program code and data constants from being read or altered across the C2 interface.

A Security Lock Byte located at the last byte of Flash user space offers protection of the Flash program memory from access (reads, writes, or erases) by unprotected code or the C2 interface. The Flash security mechanism allows the user to lock n 512-byte Flash pages, starting at page 0 (addresses 0x0000 to 0x01FF), where n is the ones complement number represented by the Security Lock Byte. Note that the page containing the Flash Security Lock Byte is unlocked when no other Flash pages are locked (all bits of the Lock Byte are 1) and locked when any other Flash pages are locked (any bit of the Lock Byte is 0). See example in Figure 14.1.

| Security Lock Byte: | 11111101b |
|---------------------|--|
| 1s Complement: | 0000010b |
| Flash pages locked: | 3 (First two Flash pages + Lock Byte Page) |

Table 21.2. Standard CAN Registers and Reset Values

Notes:

1. Read-only register.

2. Write-enabled by CCE.

3. The reset value of CAN0TST could also be r0000000b, where r signifies the value of the CAN RX pin.

4. Write-enabled by Test.

SFR Definition 23.3. SBUF0: Serial (UART0) Port Data Buffer

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|------------|---|---|---|---|---|---|---|
| Name | SBUF0[7:0] | | | | | | | |
| Туре | R/W | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

SFR Address = 0x99; SFR Page = 0x00

| Bit | Name | Function |
|-----|------------|---|
| 7:0 | SBUF0[7:0] | Serial Data Buffer Bits 7–0 (MSB–LSB). |
| | | This SFR accesses two registers; a transmit shift register and a receive latch register. When data is written to SBUF0, it goes to the transmit shift register and is held for serial transmission. Writing a byte to SBUF0 initiates the transmission. A read of SBUF0 returns the contents of the receive latch. |

SFR Definition 23.4. SBCON0: UART0 Baud Rate Generator Control

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|----------|--------|----------|----------|----------|----------|------|--------|
| Name | Reserved | SB0RUN | Reserved | Reserved | Reserved | Reserved | SB0P | S[1:0] |
| Туре | R/W | R/W | R/W | R/W | R/W | R/W | R/ | W |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

SFR Address = 0xAB; SFR Page = 0x0F

| Bit | Name | Function |
|-----|------------|---|
| 7 | Reserved | Read = 0b; Must Write 0b; |
| 6 | SB0RUN | Baud Rate Generator Enable. |
| | | 0: Baud Rate Generator disabled. UART0 will not function. |
| | | 1: Baud Rate Generator enabled. |
| 5:2 | Reserved | Read = 0000b; Must Write = 0000b; |
| 1:0 | SB0PS[1:0] | Baud Rate Prescaler Select. |
| | | 00: Prescaler = 12. |
| | | 01: Prescaler = 4. |
| | | 10: Prescaler = 48. |
| | | 11: Prescaler = 1. |

25. Timers

Each MCU includes four counter/timers: two are 16-bit counter/timers compatible with those found in the standard 8051, and two are 16-bit auto-reload timer for use with the ADC, SMBus, or for general purpose use. These timers can be used to measure time intervals, count external events and generate periodic interrupt requests. Timer 0 and Timer 1 are nearly identical and have four primary modes of operation. Timer 2 and Timer 3 offer 16-bit and split 8-bit timer functionality with auto-reload.

| Timer 0 and Timer 1 Modes | Timer 2 Modes | Timer 3 Modes |
|---|-----------------------------------|-----------------------------------|
| 13-bit counter/timer | 16-bit timer with auto-reload | 16-bit timer with auto-reload |
| 16-bit counter/timer | | |
| 8-bit counter/timer with auto-reload | Two 8-bit timers with auto-reload | Two 8-bit timers with auto-reload |
| Two 8-bit counter/timers (Timer 0 only) | | |

Timers 0 and 1 may be clocked by one of five sources, determined by the Timer Mode Select bits (T1M–T0M) and the Clock Scale bits (SCA1–SCA0). The Clock Scale bits define a pre-scaled clock from which Timer 0 and/or Timer 1 may be clocked (See SFR Definition 25.1 for pre-scaled clock selection).Timer 0/1 may then be configured to use this pre-scaled clock signal or the system clock.

Timer 2 and Timer 3 may be clocked by the system clock, the system clock divided by 12, or the external oscillator clock source divided by 8.

Timer 0 and Timer 1 may also be operated as counters. When functioning as a counter, a counter/timer register is incremented on each high-to-low transition at the selected input pin (T0 or T1). Events with a frequency of up to one-fourth the system clock frequency can be counted. The input signal need not be periodic, but it should be held at a given level for at least two full system clock cycles to ensure the level is properly sampled.

25.1.4. Mode 3: Two 8-bit Counter/Timers (Timer 0 Only)

In Mode 3, Timer 0 is configured as two separate 8-bit counter/timers held in TL0 and TH0. The counter/timer in TL0 is controlled using the Timer 0 control/status bits in TCON and TMOD: TR0, C/T0, GATE0 and TF0. TL0 can use either the system clock or an external input signal as its timebase. The TH0 register is restricted to a timer function sourced by the system clock or prescaled clock. TH0 is enabled using the Timer 1 run control bit TR1. TH0 sets the Timer 1 overflow flag TF1 on overflow and thus controls the Timer 1 interrupt.

Timer 1 is inactive in Mode 3. When Timer 0 is operating in Mode 3, Timer 1 can be operated in Modes 0, 1 or 2, but cannot be clocked by external signals nor set the TF1 flag and generate an interrupt. However, the Timer 1 overflow can be used to generate baud rates for the SMBus and/or UART, and/or initiate ADC conversions. While Timer 0 is operating in Mode 3, Timer 1 run control is handled through its mode settings. To run Timer 1 while Timer 0 is in Mode 3, set the Timer 1 Mode as 0, 1, or 2. To disable Timer 1, configure it for Mode 3.

25.2. Timer 2

Timer 2 is a 16-bit timer formed by two 8-bit SFRs: TMR2L (low byte) and TMR2H (high byte). Timer 2 may operate in 16-bit auto-reload mode or (split) 8-bit auto-reload mode. The T2SPLIT bit (TMR2CN.3) defines the Timer 2 operation mode.

Timer 2 may be clocked by the system clock, the system clock divided by 12, or the external oscillator source divided by 8. The external clock mode is ideal for real-time clock (RTC) functionality, where the internal oscillator drives the system clock while Timer 2 (and/or the PCA) is clocked by an external precision oscillator. Note that the external oscillator source divided by 8 is synchronized with the system clock.

25.2.1. 16-bit Timer with Auto-Reload

When T2SPLIT (TMR2CN.3) is zero, Timer 2 operates as a 16-bit timer with auto-reload. Timer 2 can be clocked by SYSCLK, SYSCLK divided by 12, or the external oscillator clock source divided by 8. As the 16-bit timer register increments and overflows from 0xFFFF to 0x0000, the 16-bit value in the Timer 2 reload registers (TMR2RLH and TMR2RLL) is loaded into the Timer 2 register as shown in Figure 25.4, and the Timer 2 High Byte Overflow Flag (TMR2CN.7) is set. If Timer 2 interrupts are enabled (if IE.5 is set), an interrupt will be generated on each Timer 2 overflow. Additionally, if Timer 2 interrupts are enabled and the TF2LEN bit is set (TMR2CN.5), an interrupt will be generated each time the lower 8 bits (TMR2L) overflow from 0xFF to 0x00.

Figure 25.4. Timer 2 16-Bit Mode Block Diagram

25.2.2. 8-bit Timers with Auto-Reload

When T2SPLIT is set, Timer 2 operates as two 8-bit timers (TMR2H and TMR2L). Both 8-bit timers operate in auto-reload mode as shown in Figure 25.5. TMR2RLL holds the reload value for TMR2L; TMR2RLH holds the reload value for TMR2H. The TR2 bit in TMR2CN handles the run control for TMR2H. TMR2L is always running when configured for 8-bit Mode.

Each 8-bit timer may be configured to use SYSCLK, SYSCLK divided by 12, or the external oscillator clock source divided by 8. The Timer 2 Clock Select bits (T2MH and T2ML in CKCON) select either SYSCLK or the clock defined by the Timer 2 External Clock Select bit (T2XCLK in TMR2CN), as follows:

SFR Definition 25.14. TMR3RLL: Timer 3 Reload Register Low Byte

| Bit | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | |
|-------------------------------------|------|--------------|---|---|---|---|---|---|--|--|
| Nam | e | TMR3RLL[7:0] | | | | | | | | |
