

Welcome to [E-XFL.COM](http://E-XFL.COM)

### What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

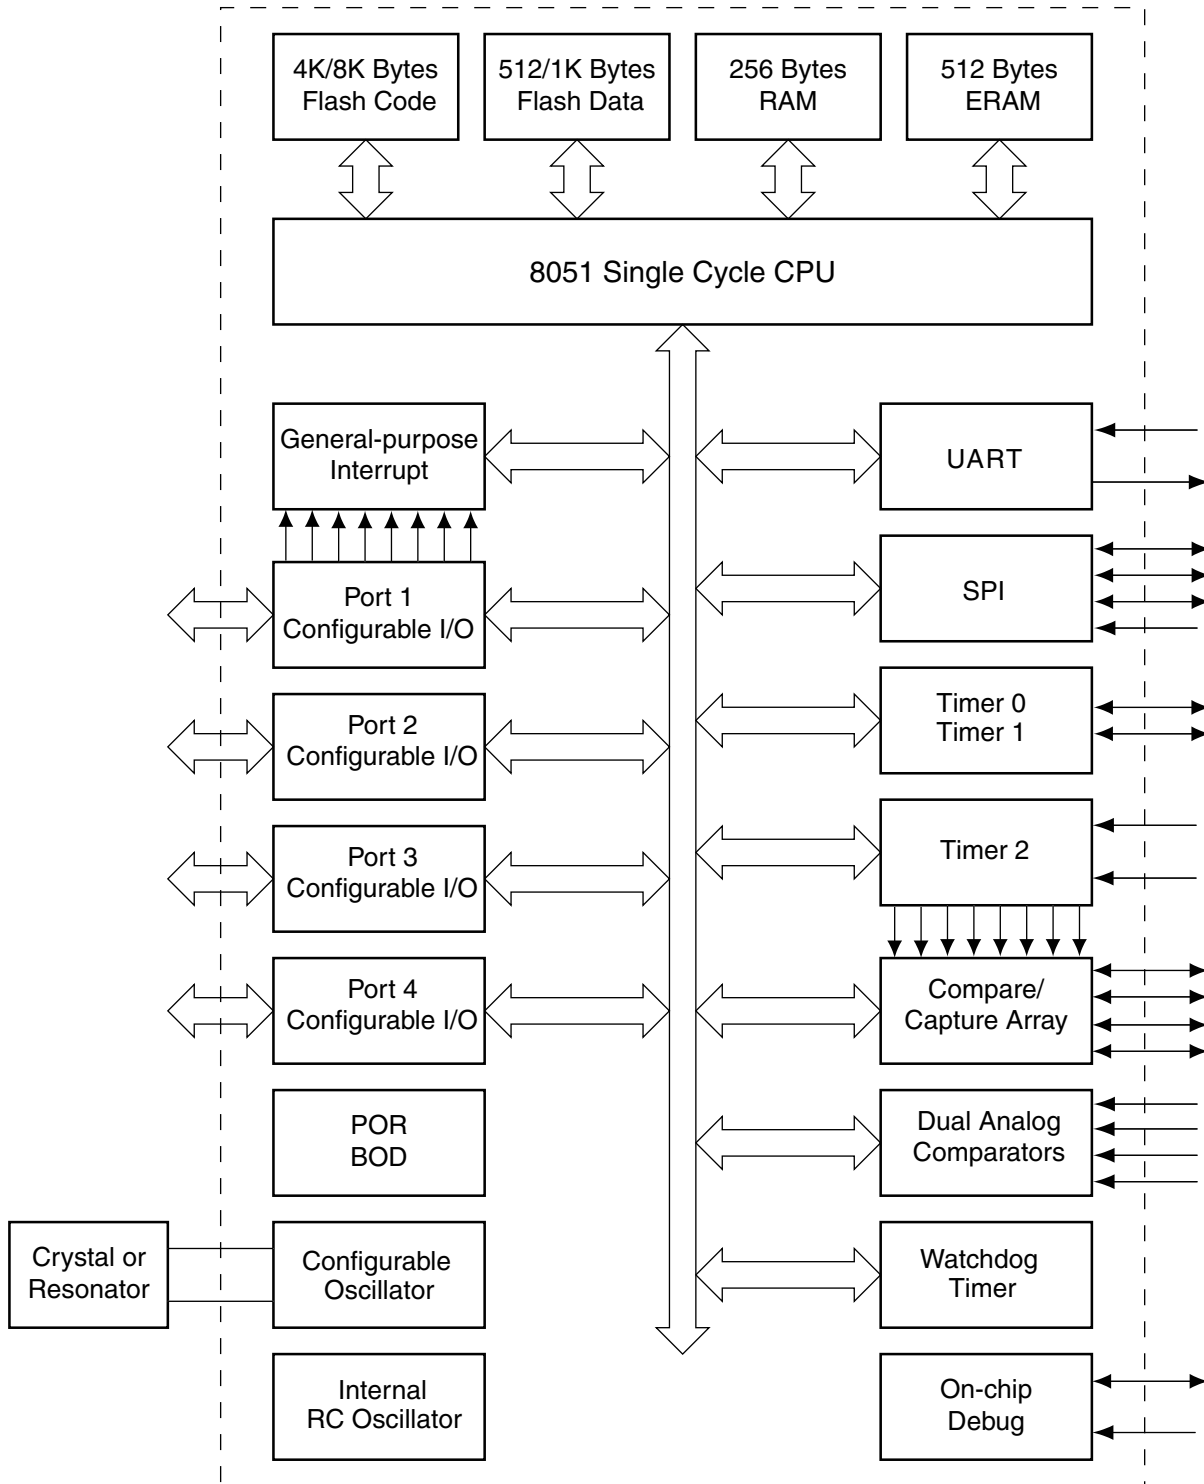

### Applications of "[Embedded - Microcontrollers](#)"

#### Details

Product Status	Active
Core Processor	8051
Core Size	8-Bit
Speed	20MHz
Connectivity	SPI, UART/USART
Peripherals	Brown-out Detect/Reset, POR, PWM, WDT
Number of I/O	30
Program Memory Size	4KB (4K x 8)
Program Memory Type	FLASH
EEPROM Size	512 x 8
RAM Size	768 x 8
Voltage - Supply (Vcc/Vdd)	2.4V ~ 5.5V
Data Converters	-
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	32-TQFP
Supplier Device Package	32-TQFP (7x7)
Purchase URL	<a href="https://www.e-xfl.com/product-detail/atmel/at89lp428-20au">https://www.e-xfl.com/product-detail/atmel/at89lp428-20au</a>

## 2.1 Block Diagram

Figure 2-1. AT89LP428/828 Block Diagram

## 4. Special Function Registers

A map of the on-chip memory area called the Special Function Register (SFR) space is shown in Table 4-1.

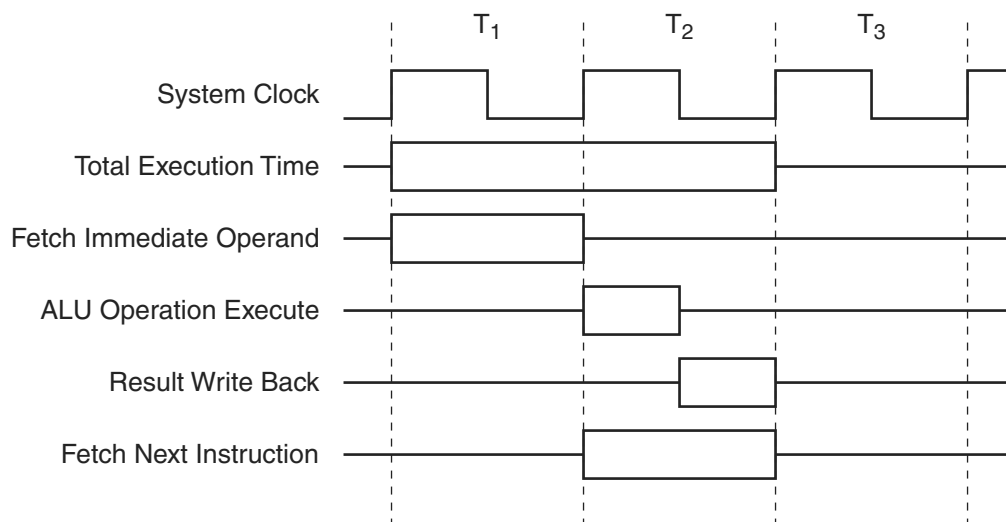

Note that not all of the addresses are occupied, and unoccupied addresses may not be implemented on the chip. Read accesses to these addresses will in general return random data, and write accesses will have an indeterminate effect. User software should not write to these unlisted locations, since they may be used in future products to invoke new features.

	0	1	2	3	4	5	6	7	

- Notes:
1. All SFRs in the left-most column are bit-addressable.
  2. Reset value is 1111 1111B when Tristate-port Fuse is enabled and 0000 0000B when disabled.

**Figure 5-3.** Two-cycle ALU Operation (Example: ADD A, #data)

## 5.1 Enhanced Dual Data Pointers

The AT89LP428/828 provides two 16-bit data pointers: DPTR0 formed by the register pair DPOL and DPOH (82H and 83H), and DPTR1 formed by the register pair DP1L and DP1H (84H and 85H). The data pointers are used by several instructions to access the program or data memories. The Data Pointer Configuration Register (DPCF) controls operation of the dual data pointers (Table 5-4). The DPS bit in DPCF selects which data pointer is currently referenced by instructions including the DPTR operand. Each data pointer may be accessed at its respective SFR addresses regardless of the DPS value. The AT89LP428/828 provides two methods for fast context switching of the data pointers:

- Bit 2 of DPCF is hard-wired as a logic 0. The DPS bit may be toggled (to switch data pointers) simply by incrementing the DPCF register, without altering other bits in the register unintentionally. This is the preferred method when only a single data pointer will be used at one time.

```
EX:   INC  DPCF    ; Toggle DPS
```

- In some cases, both data pointers must be used simultaneously. To prevent frequent toggling of DPS, the AT89LP428/828 supports a prefix notation for selecting the opposite data pointer per instruction. All DPTR instructions, with the exception of `JMP @A+DPTR`, when prefixed with an 0A5H opcode will use the inverse value of DPS ( $\overline{\text{DPS}}$ ) to select the data pointer. Some assemblers may support this operation by using the `/DPTR` operand. For example, the following code performs a block copy within EDATA:

```
MOV  DPCF, #00H    ; DPS = 0
MOV  DPTR, #SRC    ; load source address to dptr0
MOV  /DPTR, #DST   ; load destination address to dptr1
MOV  R7, #BLKSIZE ; number of bytes to copy
COPY: MOVX A, @DPTR ; read source (dptr0)
      INC  DPTR     ; next src (dptr0+1)
      MOVX @/DPTR, A ; write destination (dptr1)
      INC  /DPTR    ; next dst (dptr1+1)
      DJNZ R7, COPY
```

**Table 6-2.** CLKREG – Clock Control Register

CLKREG = 8FH				Reset Value = 0000 0000B				
Not Bit Addressable								
	TPS3	TPS2	TPS1	TPS0	CDV2	CDV1	CDV0	COE
Bit	7	6	5	4	3	2	1	0

Symbol	Function																																				
TPS [3 - 0]	Timer Prescaler. The Timer Prescaler selects the time base for Timer 0, Timer 1, Timer 2 and the Watchdog Timer. The prescaler is implemented as a 4-bit binary down counter. When the counter reaches zero it is reloaded with the value stored in the TPS bits to give a division ratio between 1 and 16. By default the timers will count every clock cycle (TPS = 0000B). To configure the timers to count at a standard 8051 rate of once every 12 clock cycles, TPS should be set to 1011B.																																				
CDV [2 - 0]	<p>System Clock Division. Determines the frequency of the system clock relative to the oscillator clock source.</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">CDIV2</th> <th style="text-align: center;">CDIV1</th> <th style="text-align: center;">CDIV0</th> <th style="text-align: left;">System Clock Frequency</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td><math>f_{OSC}/1</math></td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td><math>f_{OSC}/2</math></td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td><math>f_{OSC}/4</math></td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td><math>f_{OSC}/8</math></td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td><math>f_{OSC}/16</math></td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td><math>f_{OSC}/32</math></td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td>reserved</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td>reserved</td> </tr> </tbody> </table>	CDIV2	CDIV1	CDIV0	System Clock Frequency	0	0	0	$f_{OSC}/1$	0	0	1	$f_{OSC}/2$	0	1	0	$f_{OSC}/4$	0	1	1	$f_{OSC}/8$	1	0	0	$f_{OSC}/16$	1	0	1	$f_{OSC}/32$	1	1	0	reserved	1	1	1	reserved

1	0	0	$f_{OSC}/16$																																		
1	0	1	$f_{OSC}/32$																																		
1	1	0	reserved																																		
1	1	1	reserved																																		
COE	Clock Out Enable. Set COE to output the system clock divided by 2 on XTAL2 (P4.1). The internal RC oscillator or external clock source must be selected in order to use this feature and P4.1 must be configured as an output.																																				

## 7. Reset

During reset, all I/O Registers are set to their initial values, the port pins are tristated, and the program starts execution from the Reset Vector, 0000H. The AT89LP428/828 has five sources of reset: power-on reset, brown-out reset, external reset, watchdog reset, and software reset.

### 7.1 Power-on Reset

A Power-on Reset (POR) is generated by an on-chip detection circuit. The detection level  $V_{POR}$  is nominally 1.4V. The POR is activated whenever  $V_{CC}$  is below the detection level. The POR circuit can be used to trigger the start-up reset or to detect a supply voltage failure in devices without a brown-out detector. The POR circuit ensures that the device is reset from power-on. A power-on sequence is shown in Figure 7-1 on page 24. When  $V_{CC}$  reaches the Power-on Reset threshold voltage  $V_{POR}$ , an initialization sequence lasting  $t_{POR}$  is started. When the initialization sequence completes, the start-up timer determines how long the device is kept in POR after  $V_{CC}$  rise. The POR signal is activated again, without any delay, when  $V_{CC}$  falls below the POR threshold level. A Power-on Reset (i.e. a cold reset) will set the POF flag in PCON. The internally generated reset can be extended beyond the power-on period by holding the  $\overline{RST}$  pin low longer than the time-out.

The Timer 0 and Timer 1 Interrupts are generated by TF0 and TF1, which are set by a rollover in their respective Timer/Counter registers (except for Timer 0 in Mode 3). When a timer interrupt is generated, the on-chip hardware clears the flag that generated it when the service routine is vectored to. The Timer 2 Interrupt is generated by a logic OR of bits TF2 and EXF2 in register T2CON. Neither of these flags is cleared by hardware when the CPU vectors to the service routine. The service routine normally must determine whether TF2 or EXF2 generated the interrupt and that bit must be cleared by software.

The Serial Port Interrupt is generated by the logic OR of RI and TI in SCON. Neither of these flags is cleared by hardware when the CPU vectors to the service routine. The service routine normally must determine whether RI or TI generated the interrupt and that bit must be cleared by software. The Serial Peripheral Interface Interrupt is generated by the logic OR of SPIF, MODF and TXE in SPSR. None of these flags is cleared by hardware when the CPU vectors to the service routine. The service routine normally must determine which bit generated the interrupt and that bit must be cleared by software.

A logic OR of all eight flags in the GPIF register causes the GPI. None of these flags is cleared by hardware when the service routine is vectored to. The service routine must determine which bit generated the interrupt and that bit must be cleared in software. If the interrupt was level activated, then the external requesting source must de-assert the interrupt before the flag may be cleared by software.

The CFA and CFB bits in ACSRA and ACSRB respectively generate the Comparator Interrupt. The service routine must normally determine whether CFA or CFB generated the interrupt, and the bit must be cleared by software.

A logic OR of the four least significant bits in the T2CCF register causes the Compare/Capture Array Interrupt. None of these flags is cleared by hardware when the service routine is vectored to. The service routine must determine which bit generated the interrupt and that bit must be cleared in software.

All of the bits that generate interrupts can be set or cleared by software, with the same result as though they had been set or cleared by hardware. That is, interrupts can be generated and pending interrupts can be canceled in software.

**Table 9-1.** Interrupt Vector Addresses

Interrupt	Source	Vector Address
System Reset	RST or POR or BOD	0000H
External Interrupt 0	IE0	0003H
Timer 0 Overflow	TF0	000BH
External Interrupt 1	IE1	0013H
Timer 1 Overflow	TF1	001BH
Serial Port Interrupt	RI or TI	0023H
Timer 2 Interrupt	TF2 or EXF2	002BH
Analog Comparator Interrupt	CFA or CFB	0033H
General-purpose Interrupt	GPIF <sub>7-0</sub>	003BH
Compare/Capture Array Interrupt	T2CCF <sub>3-0</sub>	0043H
Serial Peripheral Interface Interrupt	SPIF or MODF or TXE	004BH

**Table 10-3.** Port Configuration Registers

Port	Port Data	Port Configuration
1	P1 (90H)	P1M0 (C2H), P1M1 (C3H)
2	P2 (A0H)	P2M0 (C4H), P2M1 (C5H)
3	P3 (B0H)	P3M0 (C6H), P3M1 (C7H)
4	P4 (C0H)	P4M0 (BEH), P4M1 (BFH)

### 10.1.1 Quasi-bidirectional Output

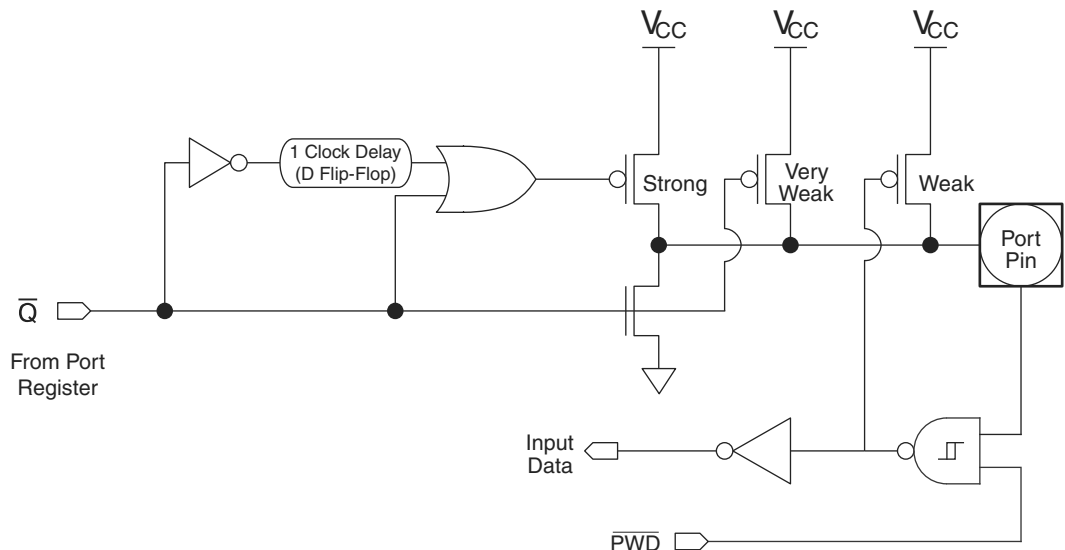

Port pins in quasi-bidirectional output mode function similar to standard 8051 port pins. A Quasi-bidirectional port can be used both as an input and output without the need to reconfigure the port. This is possible because when the port outputs a logic high, it is weakly driven, allowing an external device to pull the pin low. When the pin is driven low, it is driven strongly and able to sink a large current. There are three pull-up transistors in the quasi-bidirectional output that serve different purposes.

One of these pull-ups, called the “very weak” pull-up, is turned on whenever the port latch for the pin contains a logic “1”. This very weak pull-up sources a very small current that will pull the pin high if it is left floating.

A second pull-up, called the “weak” pull-up, is turned on when the port latch for the pin contains a logic “1” and the pin itself is also at a logic “1” level. This pull-up provides the primary source current for a quasi-bidirectional pin that is outputting a “1”. If this pin is pulled low by an external device, this weak pull-up turns off, and only the very weak pull-up remains on. In order to pull the pin low under these conditions, the external device has to sink enough current to overpower the weak pull-up and pull the port pin below its input threshold voltage.

The third pull-up is referred to as the “strong” pull-up. This pull-up is used to speed up low-to-high transitions on a quasi-bidirectional port pin when the port latch changes from a logic “0” to a logic “1”. When this occurs, the strong pull-up turns on for two CPU clocks quickly pulling the port pin high. The quasi-bidirectional port configuration is shown in Figure 10-1.

**Figure 10-1.** Quasi-bidirectional Output

### 10.3 Port Read-Modify-Write

A read from a port will read either the state of the pins or the state of the port register depending on which instruction is used. Simple read instructions will always access the port pins directly. Read-modify-write instructions, which read a value, possibly modify it, and then write it back, will always access the port register. This includes bit write instructions such as CLR or SETB as they actually read the entire port, modify a single bit, then write the data back to the entire port. See Table 10-4 for a complete list of Read-modify-write instructions which may access the ports.

**Table 10-4.** Port Read-Modify-Write Instructions

Mnemonic	Instruction	Example
ANL	Logical AND	ANL P1, A
ORL	Logical OR	ORL P1, A
XRL	Logical EX-OR	XRL P1, A
JBC	Jump if bit set and clear bit	JBC P3.0, LABEL
CPL	Complement bit	CPL P3.1
INC	Increment	INC P1
DEC	Decrement	DEC P3
DJNZ	Decrement and jump if not zero	DJNZ P3, LABEL
MOV PX.Y, C	Move carry to bit Y of Port X	MOV P1.0, C
CLR PX.Y	Clear bit Y of Port X	CLR P1.1
SETB PX.Y	Set bit Y of Port X	SETB P3.2

### 10.4 Port Alternate Functions

Most general-purpose digital I/O pins of the AT89LP428/828 share functionality with the various I/Os needed for the peripheral units. Table 10-6 lists the alternate functions of the port pins. Alternate functions are connected to the pins in a logic AND fashion. In order to enable the alternate function on a port pin, that pin must have a “1” in its corresponding port register bit, otherwise the input/output will always be “0”. However, alternate functions may be temporarily forced to “0” by clearing the associated port bit, provided that the pin is not in input-only mode. Furthermore, each pin must be configured for the correct input/output mode as required by its peripheral before it may be used as such. Table 10-5 shows how to configure a generic pin for use with an alternate function.

**Table 10-5.** Alternate Function Configurations for Pin y of Port x

PxM0.y	PxM1.y	Px.y	I/O Mode
0	0	1	Bidirectional (internal pull-up)
0	1	1	Output
1	0	X	Input
1	1	1	Bidirectional (external pull-up)

## 12. Enhanced Timer 2

The AT89LP428/828 includes a 16-bit Timer/Counter 2 with the following features:

- 16-bit timer/counter with one 16-bit reload/capture register
- One external reload/capture input
- Up/Down counting mode with external direction control
- UART baud rate generation
- Output-pin toggle on timer overflow
- Dual slope symmetric operating modes

Timer 2 is a 16-bit Timer/Counter that can operate as either a timer or an event counter. The type of operation is selected by bit  $C/\overline{T2}$  in the SFR T2CON. Timer 2 has three operating modes: capture, auto-reload (up or down counting), and baud rate generator. The modes are selected by bits in T2CON and T2MOD, as shown in Table 12-3. Timer 2 also serves as the time base for the Compare/Capture Array (see “Compare/Capture Array” on page 61).

Timer 2 consists of two 8-bit registers, TH2 and TL2. In the Timer function, the register is incremented every clock cycle. Since a clock cycle consists of one oscillator period, the count rate is equal to the oscillator frequency. The timer rate can be prescaled by a value between 1 and 16 using the Timer Prescaler (see Table 6-2 on page 23).

In the Counter function, the register is incremented in response to a 1-to-0 transition at its corresponding external input pin, T2. In this function, the external input is sampled every clock cycle. When the samples show a high in one cycle and a low in the next cycle, the count is incremented. The new count value appears in the register during the cycle following the one in which the transition was detected. Since two clock cycles are required to recognize a 1-to-0 transition, the maximum count rate is 1/2 of the oscillator frequency. To ensure that a given level is sampled at least once before it changes, the level should be held for at least one full clock cycle.

**Table 12-1.** Timer 2 Operating Modes

RCLK + TCLK	CP/RL2	DCEN	T2OE	TR2	Mode
0	0	0	0	1	16-bit Auto-reload
0	0	1	0	1	16-bit Auto-reload Up-down
0	1	X	0	1	16-bit Capture
1	X	X	X	1	Baud Rate Generator
X	X	X	1	1	Frequency Generator
X	X	X	X	0	(Off)

The following definitions for Timer 2 are used in the subsequent paragraphs:

**Table 12-2.** Timer 2 Definitions

Symbol	Definition
MIN	0000H
MAX	FFFFH
BOTTOM	16-bit value of {RCAP2H,RCAP2L} (standard modes)
TOP	16-bit value of {RCAP2H,RCAP2L} (enhanced modes)

1	0	Dual-slope with single update (up-down count: MIN →TOP →MIN )																																										
1	1	Dual-slope with double update (up-down count: MIN →TOP →MIN )																																										
T2OE	Timer 2 Output Enable. When T2OE = 1 and C/T2 = 0, the T2 pin will toggle after every Timer 2 overflow.																																											
DCEN	Timer 2 Down Count Enable. When Timer 2 operates in Auto-reload mode and EXEN2 = 1, setting DCEN = 1 will cause Timer 2 to count up or down depending on the state of T2EX.																																											

Figure 12-6. Timer 2 Waveform: Dual Slope Modes

### 12.4 Baud Rate Generator

Timer 2 is selected as the baud rate generator by setting TCLK and/or RCLK in T2CON (Table 12-3 on page 53). Note that the baud rates for transmit and receive can be different if Timer 2 is used for the receiver or transmitter and Timer 1 is used for the other function. Setting RCLK and/or TCLK puts Timer 2 into its baud rate generator mode, as shown in Figure 12-7.

The baud rate generator mode is similar to the auto-reload mode, in that a rollover in TH2 causes the Timer 2 registers to be reloaded with the 16-bit value in registers RCAP2H and RCAP2L, which are preset by software.

The baud rates in UART modes 1 and 3 are determined by Timer 2's overflow rate according to the following equation.

$$\text{Modes 1 and 3 Baud Rates} = \frac{\text{Timer 2 Overflow Rate}}{16}$$

The Timer can be configured for either timer or counter operation. In most applications, it is configured for timer operation ( $CP/\overline{T2} = 0$ ). The baud rate formulas are given below

$$T2CM = 00B \quad \text{Modes 1, 3 Baud Rate} = \frac{\text{Oscillator Frequency}}{16 \times (TPS + 1) \times [65536 - (RCAP2H, RCAP2L)]}$$

$$T2CM = 01B \quad \text{Modes 1, 3 Baud Rate} = \frac{\text{Oscillator Frequency}}{16 \times (TPS + 1) \times [(RCAP2H, RCAP2L) + 1]}$$

where (RCAP2H, RCAP2L) is the content of RCAP2H and RCAP2L taken as a 16-bit unsigned integer.

**Table 13-5.** T2CCF – Timer/Counter 2 Compare/Capture Flags

T2CCF Address = 0D5H					Reset Value = XXXX 0000B			
Not Bit Addressable								
	–	–	–	–	CCFD	CCFC	CCFB	CCFA
Bit	7	6	5	4	3	2	1	0

  

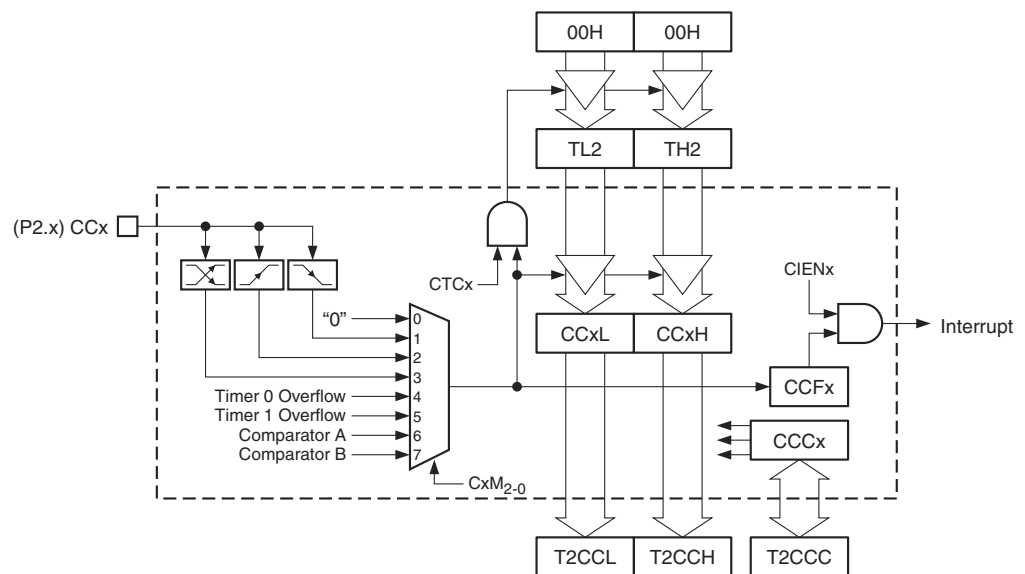

Symbol	Function
CCFD	Channel D Compare/Capture Interrupt Flag. Set by a compare/capture event on channel D. Must be cleared by software. CCFD will generate an interrupt when CIEND = 1 and ECC = 1.
CCFC	Channel C Compare/Capture Interrupt Flag. Set by a compare/capture event on channel C. Must be cleared by software. CCFC will generate an interrupt when CIENC = 1 and ECC = 1.
CCFB	Channel B Compare/Capture Interrupt Flag. Set by a compare/capture event on channel B. Must be cleared by software. CCFB will generate an interrupt when CIENB = 1 and ECC = 1.
CCFA	Channel A Compare/Capture Interrupt Flag. Set by a compare/capture event on channel A. Must be cleared by software. CCFA will generate an interrupt when CIENA = 1 and ECC = 1.

### 13.2 Input Capture Mode

The Compare/Capture Array provides a variety of capture modes suitable for time-stamping events or performing measurements of pulse width, frequency, slope, etc. The CCA channels are configured for capture mode by clearing the CCMx bit in the associated CCCx register to 0. Each time a capture event occurs, the contents of Timer 2 (TH2 and TL2) are transferred to the 16-bit data register of the corresponding channel, and the channel's interrupt flag CCFx is set in T2CCF. Optionally, the capture event may also clear Timer 2 to 0000H by setting the CTCx bit in CCCx. The capture event is defined by the CxM<sub>2-0</sub> bits in CCCx and may be either externally or internally generated. A diagram of a CCA channel in capture mode is shown in Figure 13-2.

**Figure 13-2.** CCA Capture Mode Diagram

13.3.1 Waveform Generation

Each CCA channel has an associated external compare output pin: CCA (P2.0), CCB (P2.1), CCC (P2.2) and CCD (P2.3). The  $CxM_{2-0}$  bits in  $CCCx$  determine what action is taken when a compare event occurs. The output pin may be set to 1, cleared to 0 or toggled. Output actions take place even if the interrupt is disabled; however, the associated I/O pin must be set to the desired output mode before the compare event occurs. The state of the compare outputs are initialized to 1 by reset.

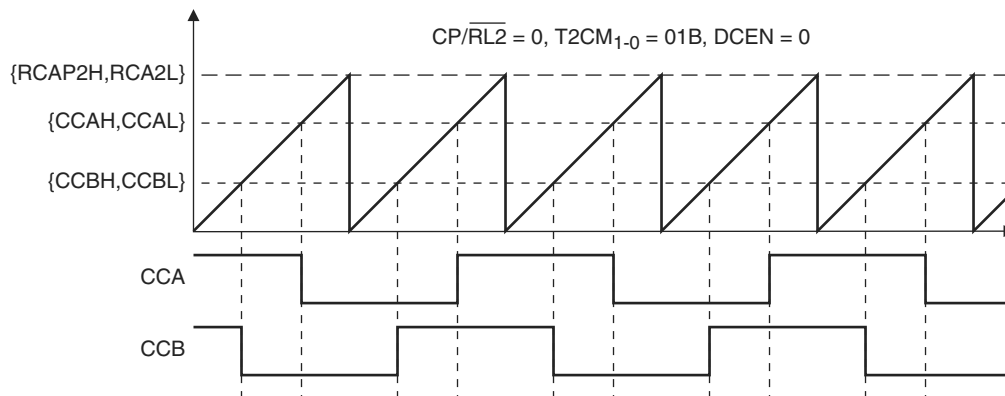

Multiple compare events per channel can occur within a single time period, provided that the software has time to update the compare value before the timer reaches the next compare point. In this case other interrupts should be disabled or the CCA interrupt given a higher priority in order to ensure that the interrupt is serviced in time.

A wide range of waveform generation configurations are possible using the various operating modes of Timer 2 and the CCA. Some example configurations are detailed below. Pulse width modulation is a special case of output compare. See “Pulse Width Modulation Mode” on page 68 for more details of PWM operation.

13.3.1.1 Normal Mode

The simplest waveform mode is when  $CP/\overline{RL2} = 0$  and  $T2CM_{1-0} = 01B$ . In this mode the frequency of the output is determined by the TOP value stored in RCAP2L and RCAP2H and output edges occur at fractions of the timer period. Figure 13-4 shows an example of outputting two waveforms of the same frequency but different phase by using the toggle on match action. More complex waveforms are achieved by changing the TOP value and the compare values more frequently.

Figure 13-4. Normal Mode Waveform Example

13.3.1.2 Clear-Timer-on-Compare Mode

Clear-Timer-on-Compare (CTC) mode occurs when the  $CTCx$  bit of a compare channel is set to one. CTC mode works best when Timer 2 is in capture mode ( $CP/\overline{RL2} = 1$ ) to allow the full range of compare values. In CTC mode, the compare value defines the interval between output events because the timer is cleared after every compare match. Figure 13-5 shows an example waveform using the toggle on match action in CTC mode.

interrupted by a data byte. An address byte, however, interrupts all slaves. Each slave can examine the received byte and see if it is being addressed. The addressed slave clears its SM2 bit and prepares to receive the data bytes that follows. The slaves that are not addressed set their SM2 bits and ignore the data bytes.

The SM2 bit can be used to check the validity of the stop bit in Mode 1. In a Mode 1 reception, if SM2 = 1, the receive interrupt is not activated unless a valid stop bit is received.

**Table 16-1.** SCON – Serial Port Control Register

SCON Address = 98H		Reset Value = 0000 0000B

(SMOD0 = 0/1) <sup>(1)</sup>								

Symbol	Function																									
FE	Framing error bit. This bit is set by the receiver when an invalid stop bit is detected. The FE bit is not cleared by valid frames and must be cleared by software. The SMOD0 bit must be set to enable access to the FE bit. FE will be set regardless of the state of SMOD0.																									
SM0	Serial Port Mode Bit 0, (SMOD0 must = 0 to access bit SM0)																									
SM1	Serial Port Mode Bit 1																									
	<table border="1"> <thead> <tr> <th>SM0</th> <th>SM1</th> <th>Mode</th> <th>Description</th> <th>Baud Rate<sup>(2)</sup></th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>shift register</td> <td><math>f_{osc}/2</math> or <math>f_{osc}/4</math> or Timer 1</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>8-bit UART</td> <td>variable (Timer 1 or Timer 2)</td> </tr> <tr> <td>1</td> <td>0</td> <td>2</td> <td>9-bit UART</td> <td><math>f_{osc}/32</math> or <math>f_{osc}/16</math></td> </tr> <tr> <td>1</td> <td>1</td> <td>3</td> <td>9-bit UART</td> <td>variable (Timer 1 or Timer 2)</td> </tr> </tbody> </table>	SM0	SM1	Mode	Description	Baud Rate <sup>(2)</sup>	0	0	0	shift register	$f_{osc}/2$ or $f_{osc}/4$ or Timer 1	0	1	1	8-bit UART	variable (Timer 1 or Timer 2)	1	0	2	9-bit UART	$f_{osc}/32$ or $f_{osc}/16$	1	1	3	9-bit UART	variable (Timer 1 or Timer 2)
	SM0	SM1	Mode	Description	Baud Rate <sup>(2)</sup>																					
	0	0	0	shift register	$f_{osc}/2$ or $f_{osc}/4$ or Timer 1																					
0	1	1	8-bit UART	variable (Timer 1 or Timer 2)																						
1	0	2	9-bit UART	$f_{osc}/32$ or $f_{osc}/16$																						
1	1	3	9-bit UART	variable (Timer 1 or Timer 2)																						
SM2	Enables the Automatic Address Recognition feature in Modes 2 or 3. If SM2 = 1 then RI will not be set unless the received 9th data bit (RB8) is 1, indicating an address, and the received byte is a Given or Broadcast Address. In Mode 1, if SM2 = 1 then RI will not be activated unless a valid stop bit was received, and the received byte is a Given or Broadcast Address. In Mode 0, SM2 determines the idle state of the shift clock such that the clock is the inverse of SM2, i.e. when SM2 = 0 the clock idles high and when SM2 = 1 the clock idles low.																									
REN	Enables serial reception. Set by software to enable reception. Clear by software to disable reception.																									
TB8	The 9th data bit that will be transmitted in Modes 2 and 3. Set or clear by software as desired. In Mode 0, setting TB8 enables Timer 1 as the shift clock generator.																									
RB8	In Modes 2 and 3, the 9th data bit that was received. In Mode 1, if SM2 = 0, RB8 is the stop bit that was received. In Mode 0, RB8 is not used.																									
T1	Transmit interrupt flag. Set by hardware at the end of the 8th bit time in Mode 0, or at the beginning of the stop bit in the other modes, in any serial transmission. Must be cleared by software.																									
RI	Receive interrupt flag. Set by hardware at the end of the 8th bit time in Mode 0, or halfway through the stop bit time in the other modes, in any serial reception (except see SM2). Must be cleared by software.																									

- Notes: 1. SMOD0 is located at PCON.6.  
 2.  $f_{osc}$  = oscillator frequency. The baud rate depends on SMOD1 (PCON.7).

Reception is initiated by the condition  $REN = 1$  and  $R1 = 0$ . At the next clock cycle, the RX Control unit writes the bits 11111110 to the receive shift register and activates RECEIVE in the next clock phase. RECEIVE enables Shift Clock to alternate output function line of P3.1. As data bits come in from the right, “1”s shift out to the left. When the “0” that was initially loaded into the right-most position arrives at the left-most position in the shift register, it flags the RX Control block to do one last shift and load SBUF. Then RECEIVE is cleared and RI is set.

The relationship between the shift clock and data is determined by the combination of the SM2 and SMOD1 bits as listed in Table 16-5 and shown in Figure 16-2. The SM2 bit determines the idle state of the clock when not currently transmitting/receiving. The SMOD1 bit determines if the output data is stable for both edges of the clock, or just one.

**Table 16-5.** Mode 0 Clock and Data Modes

SM2	SMOD1	Clock Idle	Data Changed	Data Sampled
0	0	High	While clock is high	Positive edge of clock
0	1	High	Negative edge of clock	Positive edge of clock
1	0	Low	While clock is low	Negative edge of clock
1	1	Low	Negative edge of clock	Positive edge of clock

### 17.3 Pin Configuration

When the SPI is enabled (SPE = 1), the data direction of the MOSI, MISO, SCK, and SS pins is automatically overridden according to the MSTR bit as shown in Table 17-1. The user doesn't need to reconfigure the pins when switching from master to slave or vice-versa. For more details on port configuration, refer to "Port Configuration" on page 35.

**Table 17-1.** SPI Pin Configuration and Behavior when SPE = 1

Pin	Mode	Master (MSTR = 1)	Slave (MSTR = 0)
SCK	Quasi-bidirectional	Output	Input (Internal Pull-up)
	Push-pull Output	Output	Input (Tristate)
	Input-only	No output (Tristated)	Input (Tristate)
	Open-drain Output	Output	Input (External Pull-up)
MOSI	Quasi-bidirectional	Output <sup>(1)</sup>	Input (Internal Pull-up)
	Push-pull Output	Output <sup>(2)</sup>	Input (Tristate)
	Input-only	No output (Tristated)	Input (Tristate)
	Open-drain Output	Output <sup>(1)</sup>	Input (External Pull-up)
MISO	Quasi-bidirectional	Input (Internal Pull-up)	Output ( $\overline{SS} = 0$ ) Internal Pull-up ( $\overline{SS} = 1$ or DISSO = 1)
	Push-pull Output	Input (Tristate)	Output ( $\overline{SS} = 0$ ) Tristated ( $\overline{SS} = 1$ or DISSO = 1)
	Input-only	Input (Tristate)	No output (Tristated)
	Open-drain Output	Input (External Pull-up)	Output ( $\overline{SS} = 0$ ) External Pull-up ( $\overline{SS} = 1$ or DISSO = 1)

- Notes:
1. In these modes MOSI is active only during transfers. MOSI will be pulled high between transfers to allow other masters to control the line.
  2. In Push-pull mode MOSI is active only during transfers, otherwise it is tristated to prevent line contention. A weak external pull-up may be required to prevent MOSI from floating.

**Table 18-2.** ACSR B – Analog Comparator B Control and Status Register
