
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Obsolete
Core Processor	PIC
Core Size	8-Bit
Speed	33MHz
Connectivity	UART/USART
Peripherals	POR, PWM, WDT
Number of I/O	33
Program Memory Size	4KB (2K x 16)
Program Memory Type	OTP
EEPROM Size	-
RAM Size	232 x 8
Voltage - Supply (Vcc/Vdd)	4.5V ~ 6V
Data Converters	-
Oscillator Type	External
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	44-TQFP
Supplier Device Package	44-TQFP (10x10)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic17c42at-33i-pt

NOTES:

TABLE 1-1: PIC17CXX FAMILY OF DEVICES

Features		PIC17C42	PIC17CR42	PIC17C42A	PIC17C43	PIC17CR43	PIC17C44
Maximum Frequency of Operation		25 MHz	33 MHz	33 MHz	33 MHz	33 MHz	33 MHz
Operating Voltage Range		4.5 - 5.5V	2.5 - 6.0V	2.5 - 6.0V	2.5 - 6.0V	2.5 - 6.0V	2.5 - 6.0V
Program Memory x16	(EPROM)	2K	-	2K	4K	-	8K
	(ROM)	-	2K	-	-	4K	-
Data Memory (bytes)		232	232	232	454	454	454
Hardware Multiplier (8 x 8)		-	Yes	Yes	Yes	Yes	Yes
Timer0 (16-bit + 8-bit postscaler)		Yes	Yes	Yes	Yes	Yes	Yes
Timer1 (8-bit)		Yes	Yes	Yes	Yes	Yes	Yes
Timer2 (8-bit)		Yes	Yes	Yes	Yes	Yes	Yes
Timer3 (16-bit)		Yes	Yes	Yes	Yes	Yes	Yes
Capture inputs (16-bit)		2	2	2	2	2	2
PWM outputs (up to 10-bit)		2	2	2	2	2	2
USART/SCI		Yes	Yes	Yes	Yes	Yes	Yes
Power-on Reset		Yes	Yes	Yes	Yes	Yes	Yes
Watchdog Timer		Yes	Yes	Yes	Yes	Yes	Yes
External Interrupts		Yes	Yes	Yes	Yes	Yes	Yes
Interrupt Sources		11	11	11	11	11	11
Program Memory Code Protect		Yes	Yes	Yes	Yes	Yes	Yes
I/O Pins		33	33	33	33	33	33
I/O High Current Capability	Source	25 mA	25 mA	25 mA	25 mA	25 mA	25 mA
	Sink	25 mA[(1)]	25 mA[(1)]	25 mA[(1)]	25 mA[(1)]	25 mA[(1)]	25 mA[(1)]
Package Types		40-pin DIP 44-pin PLCC 44-pin MQFP	40-pin DIP 44-pin PLCC 44-pin MQFP 44-pin TQFP	40-pin DIP 44-pin PLCC 44-pin MQFP 44-pin TQFP	40-pin DIP 44-pin PLCC 44-pin MQFP 44-pin TQFP	40-pin DIP 44-pin PLCC 44-pin MQFP 44-pin TQFP	40-pin DIP 44-pin PLCC 44-pin MQFP 44-pin TQFP

Note 1: Pins RA2 and RA3 can sink up to 60 mA.

2: General Purpose Registers (GPR) locations 20h - FFh and 120h - 1FFh are banked. All other GPRs ignore the Bank Select Register (BSR) bits.

6.4.1 INDIRECT ADDRESSING REGISTERS

The PIC17C4X has four registers for indirect addressing. These registers are:

- INDF0 and FSR0
- INDF1 and FSR1

Registers INDF0 and INDF1 are not physically implemented. Reading or writing to these registers activates indirect addressing, with the value in the corresponding FSR register being the address of the data. The FSR is an 8-bit register and allows addressing anywhere in the 256-byte data memory address range. For banked memory, the bank of memory accessed is specified by the value in the BSR.

If file INDF0 (or INDF1) itself is read indirectly via an FSR, all '0's are read (Zero bit is set). Similarly, if INDF0 (or INDF1) is written to indirectly, the operation will be equivalent to a NOP, and the status bits are not affected.

6.4.2 INDIRECT ADDRESSING OPERATION

The indirect addressing capability has been enhanced over that of the PIC16CXX family. There are two control bits associated with each FSR register. These two bits configure the FSR register to:

- Auto-decrement the value (address) in the FSR after an indirect access
- Auto-increment the value (address) in the FSR after an indirect access
- No change to the value (address) in the FSR after an indirect access

These control bits are located in the ALUSTA register. The FSR1 register is controlled by the FS3:FS2 bits and FSR0 is controlled by the FS1:FS0 bits.

When using the auto-increment or auto-decrement features, the effect on the FSR is not reflected in the ALUSTA register. For example, if the indirect address causes the FSR to equal '0', the Z bit will not be set.

If the FSR register contains a value of 0h, an indirect read will read 0h (Zero bit is set) while an indirect write will be equivalent to a NOP (status bits are not affected).

Indirect addressing allows single cycle data transfers within the entire data space. This is possible with the use of the MOVPF and MOVFP instructions, where either 'p' or 'f' is specified as INDF0 (or INDF1).

If the source or destination of the indirect address is in banked memory, the location accessed will be determined by the value in the BSR.

A simple program to clear RAM from 20h - FFh is shown in Example 6-1.

EXAMPLE 6-1: INDIRECT ADDRESSING

```
    MOVLW    0x20          ;
    MOVWF    FSR0          ; FSR0 = 20h
    BCF      ALUSTA, FS1   ; Increment FSR
    BSF      ALUSTA, FS0   ; after access
    BCF      ALUSTA, C     ; C = 0
    MOVLW    END_RAM + 1   ;
LP  CLRF     INDF0         ; Addr(FSR) = 0
    CPFSEQ   FSR0          ; FSR0 = END_RAM+1?
    GOTO     LP            ; NO, clear next
    :                      ; YES, All RAM is
    :                      ; cleared
```

6.5 Table Pointer (TBLPTRL and TBLPTRH)

File registers TBLPTRL and TBLPTRH form a 16-bit pointer to address the 64K program memory space. The table pointer is used by instructions TABLWT and TABLRD.

The TABLRD and the TABLWT instructions allow transfer of data between program and data space. The table pointer serves as the 16-bit address of the data word within the program memory. For a more complete description of these registers and the operation of Table Reads and Table Writes, see Section 7.0.

6.6 Table Latch (TBLATH, TBLATL)

The table latch (TBLAT) is a 16-bit register, with TBLATH and TBLATL referring to the high and low bytes of the register. It is not mapped into data or program memory. The table latch is used as a temporary holding latch during data transfer between program and data memory (see descriptions of instructions TABLRD, TABLWT, TLRD and TLWT). For a more complete description of these registers and the operation of Table Reads and Table Writes, see Section 7.0.

9.0 I/O PORTS

The PIC17C4X devices have five I/O ports, PORTA through PORTE. PORTB through PORTE have a corresponding Data Direction Register (DDR), which is used to configure the port pins as inputs or outputs. These five ports are made up of 33 I/O pins. Some of these ports pins are multiplexed with alternate functions.

PORTC, PORTD, and PORTE are multiplexed with the system bus. These pins are configured as the system bus when the device's configuration bits are selected to Microprocessor or Extended Microcontroller modes. In the two other microcontroller modes, these pins are general purpose I/O.

PORTA and PORTB are multiplexed with the peripheral features of the device. These peripheral features are:

- Timer modules
- Capture module
- PWM module
- USART/SCI module
- External Interrupt pin

When some of these peripheral modules are turned on, the port pin will automatically configure to the alternate function. The modules that do this are:

- PWM module
- USART/SCI module

When a pin is automatically configured as an output by a peripheral module, the pins data direction (DDR) bit is unknown. After disabling the peripheral module, the user should re-initialize the DDR bit to the desired configuration.

The other peripheral modules (which require an input) must have their data direction bit configured appropriately.

Note:	A pin that is a peripheral input, can be configured as an output (DDRx<y> is cleared). The peripheral events will be determined by the action output on the port pin.

9.1 PORTA Register

PORTA is a 6-bit wide latch. PORTA does not have a corresponding Data Direction Register (DDR).

Reading PORTA reads the status of the pins.

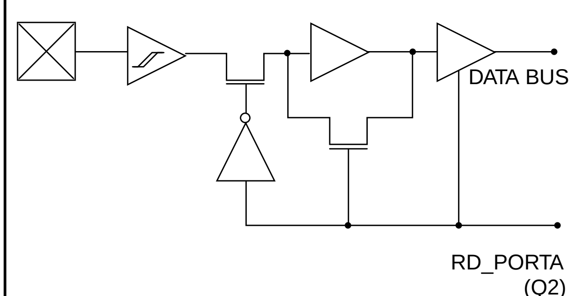
The RA1 pin is multiplexed with TMR0 clock input, and RA4 and RA5 are multiplexed with the USART functions. The control of RA4 and RA5 as outputs is automatically configured by the USART module.

9.1.1 USING RA2, RA3 AS OUTPUTS

The RA2 and RA3 pins are open drain outputs. To use the RA2 or the RA3 pin(s) as output(s), simply write to the PORTA register the desired value. A '0' will cause the pin to drive low, while a '1' will cause the pin to float (hi-impedance). An external pull-up resistor should be used to pull the pin high. Writes to PORTA will not affect the other pins.

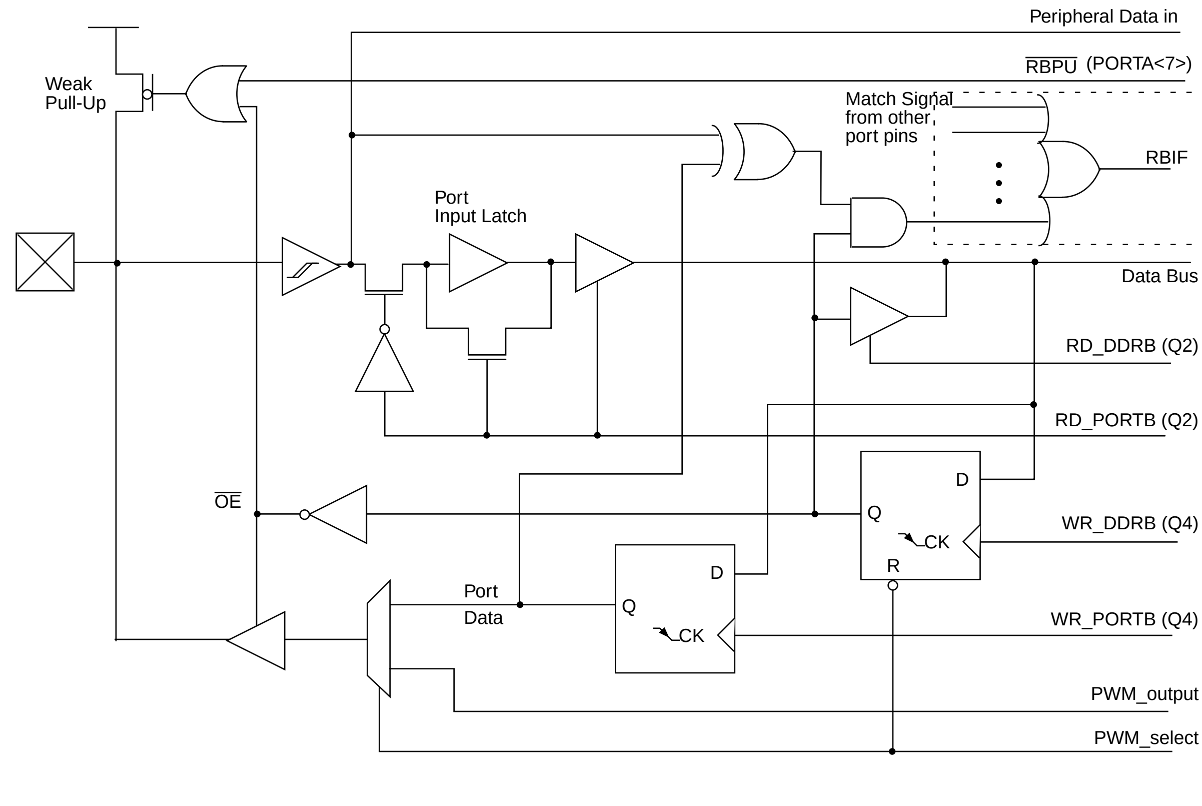
Note:	When using the RA2 or RA3 pin(s) as output(s), read-modify-write instructions (such as BCF, BSF, BTG) on PORTA are not recommended. Such operations read the port pins, do the desired operation, and then write this value to the data latch. This may inadvertently cause the RA2 or RA3 pins to switch from input to output (or vice-versa). It is recommended to use a shadow register for PORTA. Do the bit operations on this shadow register and then move it to PORTA.

FIGURE 9-1: RA0 AND RA1 BLOCK DIAGRAM



Note: I/O pins have protection diodes to V_{DD} and V_{SS}.

FIGURE 9-5: BLOCK DIAGRAM OF RB3 AND RB2 PORT PINS



Note: I/O pins have protection diodes to VDD and Vss.

12.1 Timer1 and Timer2

12.1.1 TIMER1, TIMER2 IN 8-BIT MODE

Both Timer1 and Timer2 will operate in 8-bit mode when the T16 bit is clear. These two timers can be independently configured to increment from the internal instruction cycle clock or from an external clock source on the RB4/TCLK12 pin. The timer clock source is configured by the TMRxCS bit (x = 1 for Timer1 or = 2 for Timer2). When TMRxCS is clear, the clock source is internal and increments once every instruction cycle (Fosc/4). When TMRxCS is set, the clock source is the RB4/TCLK12 pin, and the timer will increment on every falling edge of the RB4/TCLK12 pin.

The timer increments from 00h until it equals the Period register (PRx). It then resets to 00h at the next increment cycle. The timer interrupt flag is set when the timer is reset. TMR1 and TMR2 have individual interrupt flag bits. The TMR1 interrupt flag bit is latched into TMR1IF, and the TMR2 interrupt flag bit is latched into TMR2IF.

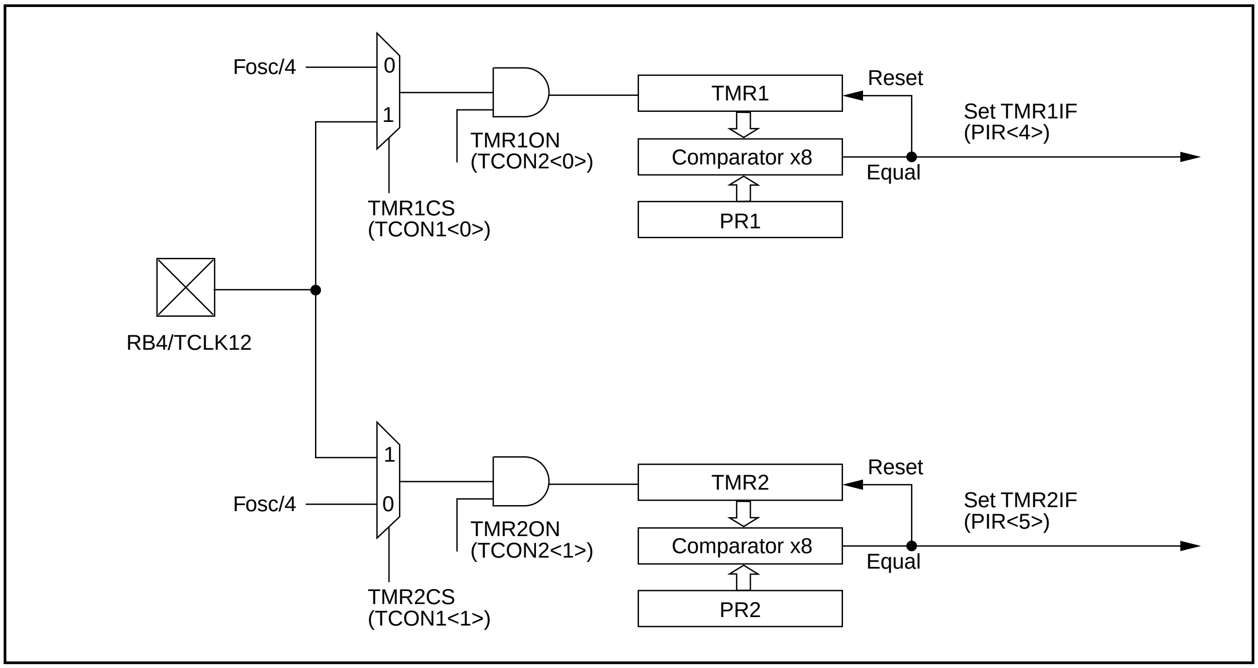
Each timer also has a corresponding interrupt enable bit (TMRxIE). The timer interrupt can be enabled by setting this bit and disabled by clearing this bit. For peripheral interrupts to be enabled, the Peripheral Interrupt Enable bit must be enabled (PEIE is set) and global interrupts must be enabled (GLINTD is cleared).

The timers can be turned on and off under software control. When the Timerx On control bit (TMRxON) is set, the timer increments from the clock source. When TMRxON is cleared, the timer is turned off and cannot cause the timer interrupt flag to be set.

12.1.1.1 EXTERNAL CLOCK INPUT FOR TIMER1 OR TIMER2

When TMRxCS is set, the clock source is the RB4/TCLK12 pin, and the timer will increment on every falling edge on the RB4/TCLK12 pin. The TCLK12 input is synchronized with internal phase clocks. This causes a delay from the time a falling edge appears on TCLK12 to the time TMR1 or TMR2 is actually incremented. For the external clock input timing requirements, see the Electrical Specification section.

FIGURE 12-3: TIMER1 AND TIMER2 IN TWO 8-BIT TIMER/COUNTER MODE



13.4 USART Synchronous Slave Mode

The synchronous slave mode differs from the master mode in the fact that the shift clock is supplied externally at the RA5/TX/CK pin (instead of being supplied internally in the master mode). This allows the device to transfer or receive data in the SLEEP mode. The slave mode is entered by clearing the CSRC (TXSTA<7>) bit.

13.4.1 USART SYNCHRONOUS SLAVE TRANSMIT

The operation of the sync master and slave modes are identical except in the case of the SLEEP mode.

If two words are written to TXREG and then the SLEEP instruction executes, the following will occur. The first word will immediately transfer to the TSR and will transmit as the shift clock is supplied. The second word will remain in TXREG. TXIF will not be set. When the first word has been shifted out of TSR, TXREG will transfer the second word to the TSR and the TXIF flag will now be set. If TXIE is enabled, the interrupt will wake the chip from SLEEP and if the global interrupt is enabled, then the program will branch to interrupt vector (0020h).

Steps to follow when setting up a Synchronous Slave Transmission:

1. Enable the synchronous slave serial port by setting the SYNC and SPEN bits and clearing the CSRC bit.
2. Clear the CREN bit.
3. If interrupts are desired, then set the TXIE bit.
4. If 9-bit transmission is desired, then set the TX9 bit.
5. Start transmission by loading data to TXREG.
6. If 9-bit transmission is selected, the ninth bit should be loaded in TX9D.
7. Enable the transmission by setting TXEN.

Writing the transmit data to the TXREG, then enabling the transmit (setting TXEN) allows transmission to start sooner then doing these two events in the reverse order.

Note: To terminate a transmission, either clear the SPEN bit, or the TXEN bit. This will reset the transmit logic, so that it will be in the proper state when transmit is re-enabled.

13.4.2 USART SYNCHRONOUS SLAVE RECEPTION

Operation of the synchronous master and slave modes are identical except in the case of the SLEEP mode. Also, SREN is a don't care in slave mode.

If receive is enabled (CREN) prior to the SLEEP instruction, then a word may be received during SLEEP. On completely receiving the word, the RSR will transfer the data to RCREG (setting RCIF) and if the RCIE bit is set, the interrupt generated will wake the chip from SLEEP. If the global interrupt is enabled, the program will branch to the interrupt vector (0020h).

Steps to follow when setting up a Synchronous Slave Reception:

1. Enable the synchronous master serial port by setting the SYNC and SPEN bits and clearing the CSRC bit.
2. If interrupts are desired, then set the RCIE bit.
3. If 9-bit reception is desired, then set the RX9 bit.
4. To enable reception, set the CREN bit.
5. The RCIF bit will be set when reception is complete and an interrupt will be generated if the RCIE bit was set.
6. Read RCSTA to get the ninth bit (if enabled) and determine if any error occurred during reception.
7. Read the 8-bit received data by reading RCREG.
8. If any error occurred, clear the error by clearing the CREN bit.

Note: To abort reception, either clear the SPEN bit, the SREN bit (when in single receive mode), or the CREN bit (when in continuous receive mode). This will reset the receive logic, so that it will be in the proper state when receive is re-enabled.

14.4.2 MINIMIZING CURRENT CONSUMPTION

To minimize current consumption, all I/O pins should be either at V_{DD}, or V_{SS}, with no external circuitry drawing current from the I/O pin. I/O pins that are hi-impedance inputs should be pulled high or low externally to avoid switching currents caused by floating inputs. The T0CKI input should be at V_{DD} or V_{SS}. The contributions from on-chip pull-ups on PORTB should also be considered, and disabled when possible.

14.5 Code Protection

The code in the program memory can be protected by selecting the microcontroller in code protected mode (PM2:PM0 = '000').

> **Note:** PM2 does not exist on the PIC17C42. To select code protected microcontroller mode, PM1:PM0 = '00'.

In this mode, instructions that are in the on-chip program memory space, can continue to read or write the program memory. An instruction that is executed outside of the internal program memory range will be inhibited from writing to or reading from program memory.

> **Note:** Microchip does not recommend code protecting windowed devices.

If the code protection bit(s) have not been programmed, the on-chip program memory can be read out for verification purposes.

MOVFP — Move f to p

Syntax: [*label*] MOVFP f,p

Operands: $0 \le f \le 255$
$0 \le p \le 31$

Operation: (f) → (p)

Status Affected: None

Encoding:

`011p`	`pppp`	`ffff`	`ffff`

Description: Move data from data memory location 'f' to data memory location 'p'. Location 'f' can be anywhere in the 256 word data space (00h to FFh) while 'p' can be 00h to 1Fh.

Either 'p' or 'f' can be WREG (a useful special situation).

`MOVFP` is particularly useful for transferring a data memory location to a peripheral register (such as the transmit buffer or an I/O port). Both 'f' and 'p' can be indirectly addressed.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Execute	Write register 'p'

Example: `MOVFP REG1, REG2`

Before Instruction
REG1 = 0x33,
REG2 = 0x11

After Instruction
REG1 = 0x33,
REG2 = 0x33

MOVLB — Move Literal to low nibble in BSR

Syntax: [*label*] MOVLB k

Operands: $0 \le k \le 15$

Operation: k → (BSR<3:0>)

Status Affected: None

Encoding:

`1011`	`1000`	`uuuu`	`kkkk`

Description: The four bit literal 'k' is loaded in the Bank Select Register (BSR). Only the low 4-bits of the Bank Select Register are affected. The upper half of the BSR is unchanged. The assembler will encode the “u” fields as '0'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'u:k'	Execute	Write literal 'k' to BSR<3:0>

Example: `MOVLB 0x5`

Before Instruction
BSR register = 0x22

After Instruction
BSR register = 0x25

Note: For the PIC17C42, only the low four bits of the BSR register are physically implemented. The upper nibble is read as '0'.

SLEEP — Enter SLEEP mode

Syntax:	[*label*] SLEEP
Operands:	None
Operation:	00h → WDT; 0 → WDT postscaler; 1 → $\overline{TO}$; 0 → $\overline{PD}$
Status Affected:	$\overline{TO}$, $\overline{PD}$
Encoding:	`0000 0000 0000 0011`
Description:	The power down status bit ($\overline{PD}$) is cleared. The time-out status bit ($\overline{TO}$) is set. Watchdog Timer and its prescaler are cleared. The processor is put into SLEEP mode with the oscillator stopped.
Words:	1
Cycles:	1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register PCLATH	Execute	NOP

<u>Example</u>: `SLEEP`

Before Instruction
- $\overline{TO}$ = ?
- $\overline{PD}$ = ?

After Instruction
- $\overline{TO}$ = 1 †
- $\overline{PD}$ = 0

† If WDT causes wake-up, this bit is cleared

SUBLW — Subtract WREG from Literal

Syntax:	[*label*] SUBLW k
Operands:	$0 \le k \le 255$
Operation:	k – (WREG) → (WREG)
Status Affected:	OV, C, DC, Z
Encoding:	`1011 0010 kkkk kkkk`
Description:	WREG is subtracted from the eight bit literal 'k'. The result is placed in WREG.
Words:	1
Cycles:	1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Execute	Write to WREG

<u>Example 1</u>: `SUBLW 0x02`

Before Instruction
- WREG = 1
- C = ?

After Instruction
- WREG = 1
- C = 1 ; result is positive
- Z = 0

<u>Example 2</u>:

Before Instruction
- WREG = 2
- C = ?

After Instruction
- WREG = 0
- C = 1 ; result is zero
- Z = 1

<u>Example 3</u>:

Before Instruction
- WREG = 3
- C = ?

After Instruction
- WREG = FF ; (2's complement)
- C = 0 ; result is negative
- Z = 1

TABLRD — Table Read

Example1: `TABLRD 1, 1, REG ;`

Before Instruction

REG	=	0x53
TBLATH	=	0xAA
TBLATL	=	0x55
TBLPTR	=	0xA356
MEMORY(TBLPTR)	=	0x1234

After Instruction (table write completion)

REG	=	0xAA
TBLATH	=	0x12
TBLATL	=	0x34
TBLPTR	=	0xA357
MEMORY(TBLPTR)	=	0x5678

Example2: `TABLRD 0, 0, REG ;`

Before Instruction

REG	=	0x53
TBLATH	=	0xAA
TBLATL	=	0x55
TBLPTR	=	0xA356
MEMORY(TBLPTR)	=	0x1234

After Instruction (table write completion)

REG	=	0x55
TBLATH	=	0x12
TBLATL	=	0x34
TBLPTR	=	0xA356
MEMORY(TBLPTR)	=	0x1234

TABLWT — Table Write

Syntax: [*label*] TABLWT t,i,f

Operands: $0 \le f \le 255$
$i \in [0,1]$
$t \in [0,1]$

Operation: If t = 0,
f → TBLATL;
If t = 1,
f → TBLATH;
TBLAT → Prog Mem (TBLPTR);
If i = 1,
TBLPTR + 1 → TBLPTR

Status Affected: None

Encoding:

1010	11ti	ffff	ffff

Description:

1. Load value in ’f’ into 16-bit table latch (TBLAT)
   If t = 0: load into low byte;
   If t = 1: load into high byte
2. The contents of TBLAT is written to the program memory location pointed to by TBLPTR
   If TBLPTR points to external program memory location, then the instruction takes two-cycle
   If TBLPTR points to an internal EPROM location, then the instruction is terminated when an interrupt is received.

> **Note:** The $\overline{MCLR}$/VPP pin must be at the programming voltage for successful programming of internal memory.
> If $\overline{MCLR}$/VPP = VDD
> the programming sequence of internal memory will be executed, but will not be successful (although the internal memory location may be disturbed)

3. The TBLPTR can be automatically incremented
   If i = 0; TBLPTR is not incremented
   If i = 1; TBLPTR is incremented

Words: 1

Cycles: 2 (many if write is to on-chip EPROM program memory)

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Execute	Write register TBLATH or TBLATL

TABLWT — Table Write

Example1: `TABLWT 0, 1, REG`

Before Instruction

REG	=	0x53
TBLATH	=	0xAA
TBLATL	=	0x55
TBLPTR	=	0xA356
MEMORY(TBLPTR)	=	0xFFFF

After Instruction (table write completion)

REG	=	0x53
TBLATH	=	0x53
TBLATL	=	0x55
TBLPTR	=	0xA357
MEMORY(TBLPTR - 1)	=	0x5355

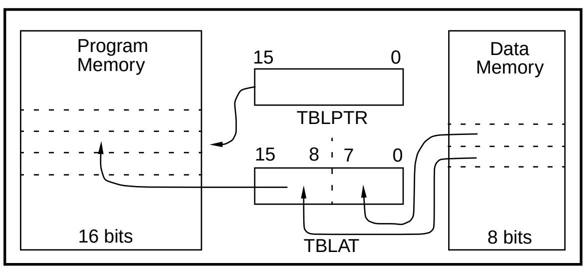
Example 2: `TABLWT 1, 0, REG`

Before Instruction

REG	=	0x53
TBLATH	=	0xAA
TBLATL	=	0x55
TBLPTR	=	0xA356
MEMORY(TBLPTR)	=	0xFFFF

After Instruction (table write completion)

REG	=	0x53
TBLATH	=	0xAA
TBLATL	=	0x53
TBLPTR	=	0xA356
MEMORY(TBLPTR)	=	0xAA53



TLRD — Table Latch Read

Syntax: [*label*] TLRD t,f

Operands: 0 ≤ f ≤ 255
t ∈ [0,1]

Operation: If t = 0,
TBLATL → f;
If t = 1,
TBLATH → f

Status Affected: None

Encoding:

`1010`	`00tx`	`ffff`	`ffff`

Description: Read data from 16-bit table latch (TBLAT) into file register 'f'. Table Latch is unaffected.

If t = 1; high byte is read

If t = 0; low byte is read

This instruction is used in conjunction with `TABLRD` to transfer data from program memory to data memory.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register TBLATH or TBLATL	Execute	Write register 'f'

Example: `TLRD t, RAM`

Before Instruction

t	=	0	
RAM	=	?	
TBLAT	=	0x00AF	(TBLATH = 0x00) (TBLATL = 0xAF)

After Instruction

RAM	=	0xAF	
TBLAT	=	0x00AF	(TBLATH = 0x00) (TBLATL = 0xAF)

Before Instruction

t	=	1	
RAM	=	?	
TBLAT	=	0x00AF	(TBLATH = 0x00) (TBLATL = 0xAF)

After Instruction

RAM	=	0x00	
TBLAT	=	0x00AF	(TBLATH = 0x00) (TBLATL = 0xAF)

DC CHARACTERISTICS			Standard Operating Conditions (unless otherwise stated) Operating temperature -40˚C ≤ T_A ≤ +85˚C for industrial and 0˚C ≤ T_A ≤ +70˚C for commercial Operating voltage V_{DD} range as described in Section 19.1				
Parameter No.	**Sym**	**Characteristic**	**Min**	**Typ†**	**Max**	**Units**	**Conditions**
		Output Low Voltage					
D080	V_{OL}	I/O ports (except RA2 and RA3)					I_{OL} = V_{DD}/1.250 mA
			–	–	0.1V_{DD}	V	4.5V ≤ V_{DD} ≤ 6.0V
			–	–	0.1V_{DD} *	V	V_{DD} = 2.5V
D081		with TTL buffer	–	–	0.4	V	I_{OL} = 6 mA, V_{DD} = 4.5V Note 6
D082		RA2 and RA3	–	–	3.0	V	I_{OL} = 60.0 mA, V_{DD} = 6.0V
D083		OSC2/CLKOUT	–	–	0.4	V	I_{OL} = 1 mA, V_{DD} = 4.5V
D084		(RC and EC osc modes)	–	–	0.1V_{DD} *	V	I_{OL} = V_{DD}/5 mA (PIC17LC43/LC44 only)
		Output High Voltage (Note 3)					
D090	V_{OH}	I/O ports (except RA2 and RA3)					I_{OH} = -V_{DD}/2.500 mA
			0.9V_{DD}	–	–	V	4.5V ≤ V_{DD} ≤ 6.0V
			0.9V_{DD} *	–	–	V	V_{DD} = 2.5V
D091		with TTL buffer	2.4	–	–	V	I_{OH} = -6.0 mA, V_{DD}=4.5V Note 6
D092		RA2 and RA3	–	–	12	V	Pulled-up to externally applied voltage
D093		OSC2/CLKOUT	2.4	–	–	V	I_{OH} = -5 mA, V_{DD} = 4.5V
D094		(RC and EC osc modes)	0.9V_{DD} *	–	–	V	I_{OH} = -V_{DD}/5 mA (PIC17LC43/LC44 only)
		Capacitive Loading Specs on Output Pins					
D100	C_{OSC2}	OSC2/CLKOUT pin	–	–	25	pF	In EC or RC osc modes when OSC2 pin is outputting CLKOUT. external clock is used to drive OSC1.
D101	C_{IO}	All I/O pins and OSC2 (in RC mode)	–	–	50	pF	
D102	C_{AD}	System Interface Bus (PORTC, PORTD and PORTE)	–	–	50	pF	In Microprocessor or Extended Microcontroller mode

* These parameters are characterized but not tested.

† Data in “Typ” column is at 5V, 25°C unless otherwise stated. These parameters are for design guidance only and are not tested.

‡ These parameters are for design guidance only and are not tested, nor characterized.

Note 1: In RC oscillator configuration, the OSC1/CLKIN pin is a Schmitt Trigger input. It is not recommended that the PIC17CXX devices be driven with external clock in RC mode.

2: The leakage current on the $\overline{MCLR}$ pin is strongly dependent on the applied voltage level. The specified levels represent normal operating conditions. Higher leakage current may be measured at different input voltages.

3: Negative current is defined as coming out of the pin.

4: These specifications are for the programming of the on-chip program memory EPROM through the use of the table write instructions. The complete programming specifications can be found in: PIC17CXX Programming Specifications (Literature number DS30139).

5: The $\overline{MCLR}$/V_{PP} pin may be kept in this range at times other than programming, but is not recommended.

6: For TTL buffers, the better of the two specifications may be used.
