

Welcome to [E-XFL.COM](https://www.e-xfl.com)

What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "[Embedded - Microcontrollers](#)"

Details

Product Status	Obsolete
Core Processor	PIC
Core Size	8-Bit
Speed	25MHz
Connectivity	UART/USART
Peripherals	POR, PWM, WDT
Number of I/O	33
Program Memory Size	8KB (4K x 16)
Program Memory Type	OTP
EEPROM Size	-
RAM Size	454 x 8
Voltage - Supply (Vcc/Vdd)	4.5V ~ 6V
Data Converters	-
Oscillator Type	External
Operating Temperature	-40°C ~ 125°C (TA)
Mounting Type	Surface Mount
Package / Case	44-TQFP
Supplier Device Package	44-TQFP (10x10)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic17c43t-25e-pt

PIC17C4X

Pin Diagrams Cont'd

PLCC

MQFP
TQFP

All devices are available in all package types, listed in Section 21.0, with the following exceptions:

- ROM devices are not available in Windowed Cerdip Packages
- TQFP is not available for the PIC17C42.

3.0 ARCHITECTURAL OVERVIEW

The high performance of the PIC17C4X can be attributed to a number of architectural features commonly found in RISC microprocessors. To begin with, the PIC17C4X uses a modified Harvard architecture. This architecture has the program and data accessed from separate memories. So the device has a program memory bus and a data memory bus. This improves bandwidth over traditional von Neumann architecture, where program and data are fetched from the same memory (accesses over the same bus). Separating program and data memory further allows instructions to be sized differently than the 8-bit wide data word. PIC17C4X opcodes are 16-bits wide, enabling single word instructions. The full 16-bit wide program memory bus fetches a 16-bit instruction in a single cycle. A two-stage pipeline overlaps fetch and execution of instructions. Consequently, all instructions execute in a single cycle (121 ns @ 33 MHz), except for program branches and two special instructions that transfer data between program and data memory.

The PIC17C4X can address up to 64K x 16 of program memory space.

The **PIC17C42** and **PIC17C42A** integrate 2K x 16 of EPROM program memory on-chip, while the **PIC17CR42** has 2K x 16 of ROM program memory on-chip.

The **PIC17C43** integrates 4K x 16 of EPROM program memory, while the **PIC17CR43** has 4K x 16 of ROM program memory.

The **PIC17C44** integrates 8K x 16 EPROM program memory.

Program execution can be internal only (microcontroller or protected microcontroller mode), external only (microprocessor mode) or both (extended microcontroller mode). Extended microcontroller mode does not allow code protection.

The PIC17CXX can directly or indirectly address its register files or data memory. All special function registers, including the Program Counter (PC) and Working Register (WREG), are mapped in the data memory. The PIC17CXX has an orthogonal (symmetrical) instruction set that makes it possible to carry out any operation on any register using any addressing mode. This symmetrical nature and lack of 'special optimal situations' make programming with the PIC17CXX simple yet efficient. In addition, the learning curve is reduced significantly.

One of the PIC17CXX family architectural enhancements from the PIC16CXX family allows two file registers to be used in some two operand instructions. This allows data to be moved directly between two registers without going through the WREG register. This increases performance and decreases program memory usage.

The PIC17CXX devices contain an 8-bit ALU and working register. The ALU is a general purpose arithmetic unit. It performs arithmetic and Boolean functions between data in the working register and any register file.

The ALU is 8-bits wide and capable of addition, subtraction, shift, and logical operations. Unless otherwise mentioned, arithmetic operations are two's complement in nature.

The WREG register is an 8-bit working register used for ALU operations.

All PIC17C4X devices (except the PIC17C42) have an 8 x 8 hardware multiplier. This multiplier generates a 16-bit result in a single cycle.

Depending on the instruction executed, the ALU may affect the values of the Carry (C), Digit Carry (DC), and Zero (Z) bits in the STATUS register. The C and DC bits operate as a borrow and digit borrow out bit, respectively, in subtraction. See the **SUBLW** and **SUBWF** instructions for examples.

Although the ALU does not perform signed arithmetic, the Overflow bit (OV) can be used to implement signed math. Signed arithmetic is comprised of a magnitude and a sign bit. The overflow bit indicates if the magnitude overflows and causes the sign bit to change state. Signed math can have greater than 7-bit values (magnitude), if more than one byte is used. The use of the overflow bit only operates on bit6 (MSb of magnitude) and bit7 (sign bit) of the value in the ALU. That is, the overflow bit is not useful if trying to implement signed math where the magnitude, for example, is 11-bits. If the signed math values are greater than 7-bits (15-, 24- or 31-bit), the algorithm must ensure that the low order bytes ignore the overflow status bit.

Care should be taken when adding and subtracting signed numbers to ensure that the correct operation is executed. Example 3-1 shows an item that must be taken into account when doing signed arithmetic on an ALU which operates as an unsigned machine.

EXAMPLE 3-1: SIGNED MATH

Hex Value	Signed Value Math	Unsigned Value Math
FFh	-127	255
+ 01h	+ 1	+ 1
= ?	= -126 (FEh)	= 0 (00h); Carry bit = 1

Signed math requires the result in REG to be FEh (-126). This would be accomplished by subtracting one as opposed to adding one.

Simplified block diagrams are shown in Figure 3-1 and Figure 3-2. The descriptions of the device pins are listed in Table 3-1.

4.0 RESET

The PIC17CXX differentiates between various kinds of reset:

- Power-on Reset (POR)
- $\overline{\text{MCLR}}$ reset during normal operation
- WDT Reset (normal operation)

Some registers are not affected in any reset condition; their status is unknown on POR and unchanged in any other reset. Most other registers are forced to a "reset state" on Power-on Reset (POR), on $\overline{\text{MCLR}}$ or WDT Reset and on $\overline{\text{MCLR}}$ reset during SLEEP. They are not affected by a WDT Reset during SLEEP, since this reset is viewed as the resumption of normal operation. The $\overline{\text{TO}}$ and $\overline{\text{PD}}$ bits are set or cleared differently in different reset situations as indicated in Table 4-3. These bits are used in software to determine the nature of reset. See Table 4-4 for a full description of reset states of all registers.

Note: While the device is in a reset state, the internal phase clock is held in the Q1 state. Any processor mode that allows external execution will force the RE0/ALE pin as a low output and the RE1/ $\overline{\text{OE}}$ and RE2/ $\overline{\text{WR}}$ pins as high outputs.

A simplified block diagram of the on-chip reset circuit is shown in Figure 4-1.

4.1 Power-on Reset (POR), Power-up Timer (PWRT), and Oscillator Start-up Timer (OST)

4.1.1 POWER-ON RESET (POR)

The Power-on Reset circuit holds the device in reset until V_{DD} is above the trip point (in the range of 1.4V - 2.3V). The PIC17C42 does not produce an internal reset when V_{DD} declines. All other devices will produce an internal reset for both rising and falling V_{DD} . To take advantage of the POR, just tie the $\overline{\text{MCLR}}/\text{VPP}$ pin directly (or through a resistor) to V_{DD} . This will eliminate external RC components usually needed to create Power-on Reset. A minimum rise time for V_{DD} is required. See Electrical Specifications for details.

4.1.2 POWER-UP TIMER (PWRT)

The Power-up Timer provides a fixed 96 ms time-out (nominal) on power-up. This occurs from rising edge of the POR signal and after the first rising edge of $\overline{\text{MCLR}}$ (detected high). The Power-up Timer operates on an internal RC oscillator. The chip is kept in RESET as long as the PWRT is active. In most cases the PWRT delay allows the V_{DD} to rise to an acceptable level.

The power-up time delay will vary from chip to chip and to V_{DD} and temperature. See DC parameters for details.

R = Readable bit
W = Writable bit
-n = Value at POR reset

PIC17C4X

NOTES:

PIC17C4X

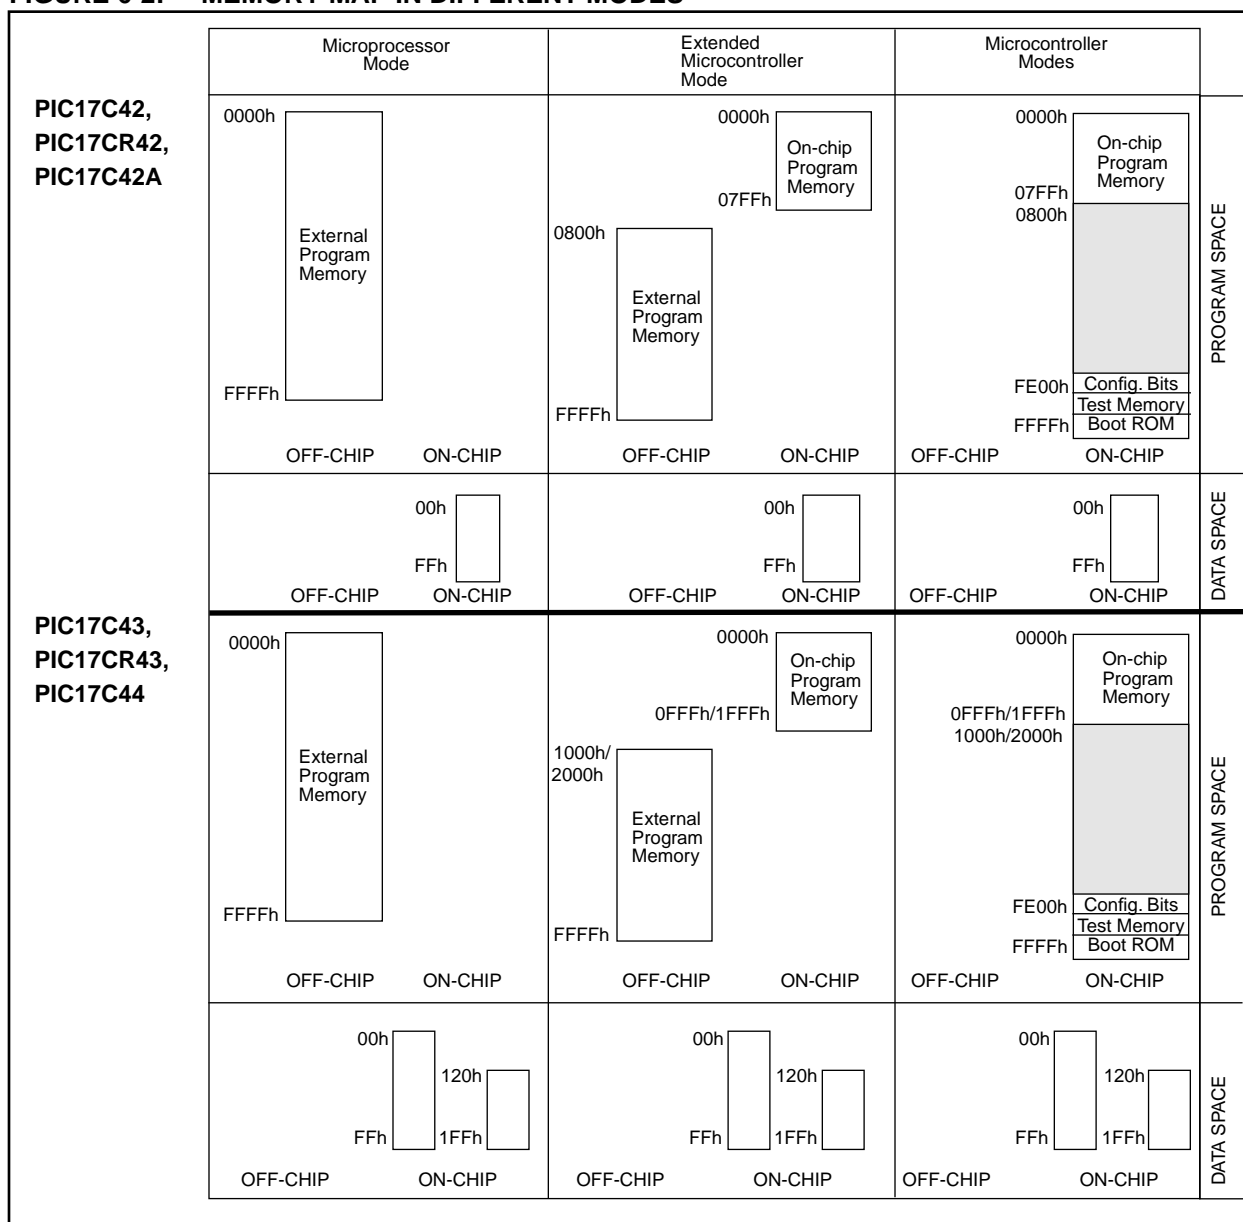

TABLE 6-1: MODE MEMORY ACCESS

Operating Mode	Internal Program Memory	Configuration Bits, Test Memory, Boot ROM
Microprocessor	No Access	No Access
Microcontroller	Access	Access
Extended Microcontroller	Access	No Access
Protected Microcontroller	Access	Access

The PIC17C4X can operate in modes where the program memory is off-chip. They are the microprocessor and extended microcontroller modes. The microprocessor mode is the default for an unprogrammed device.

Regardless of the processor mode, data memory is always on-chip.

FIGURE 6-2: MEMORY MAP IN DIFFERENT MODES

6.2.2.1 ALU STATUS REGISTER (ALUSTA)

The ALUSTA register contains the status bits of the Arithmetic and Logic Unit and the mode control bits for the indirect addressing register.

As with all the other registers, the ALUSTA register can be the destination for any instruction. If the ALUSTA register is the destination for an instruction that affects the Z, DC or C bits, then the write to these three bits is disabled. These bits are set or cleared according to the device logic. Therefore, the result of an instruction with the ALUSTA register as destination may be different than intended.

For example, `CLRF ALUSTA` will clear the upper four bits and set the Z bit. This leaves the ALUSTA register as 0000u1uu (where u = unchanged).

It is recommended, therefore, that only `BCF`, `BSF`, `SWAPF` and `MOVWF` instructions be used to alter the ALUSTA register because these instructions do not affect any status bit. To see how other instructions affect the status bits, see the "Instruction Set Summary."

Note 1: The C and DC bits operate as a borrow out bit in subtraction. See the `SUBLW` and `SUBWF` instructions for examples.

Note 2: The overflow bit will be set if the 2's complement result exceeds +127 or is less than -128.

Arithmetic and Logic Unit (ALU) is capable of carrying out arithmetic or logical operations on two operands or a single operand. All single operand instructions operate either on the WREG register or a file register. For two operand instructions, one of the operands is the WREG register and the other one is either a file register or an 8-bit immediate constant.

FIGURE 6-7: ALUSTA REGISTER (ADDRESS: 04h, UNBANKED)

R/W - 1	R/W - 1	R/W - 1	R/W - 1	R/W - x	R/W - x	R/W - x	R/W - x
FS3	FS2	FS1	FS0	OV	Z	DC	C
bit7							bit0

R = Readable bit
W = Writable bit
-n = Value at POR reset
(x = unknown)

bit 7-6: **FS3:FS2:** FSR1 Mode Select bits
 00 = Post auto-decrement FSR1 value
 01 = Post auto-increment FSR1 value
 1x = FSR1 value does not change

bit 5-4: **FS1:FS0:** FSR0 Mode Select bits
 00 = Post auto-decrement FSR0 value
 01 = Post auto-increment FSR0 value
 1x = FSR0 value does not change

bit 3: **OV:** Overflow bit
 This bit is used for signed arithmetic (2's complement). It indicates an overflow of the 7-bit magnitude, which causes the sign bit (bit7) to change state.
 1 = Overflow occurred for signed arithmetic, (in this arithmetic operation)
 0 = No overflow occurred

bit 2: **Z:** Zero bit
 1 = The result of an arithmetic or logic operation is zero
 0 = The results of an arithmetic or logic operation is not zero

bit 1: **DC:** Digit carry/borrow bit
 For `ADDWF` and `ADDLW` instructions.
 1 = A carry-out from the 4th low order bit of the result occurred
 0 = No carry-out from the 4th low order bit of the result
 Note: For borrow the polarity is reversed.

bit 0: **C:** carry/borrow bit
 For `ADDWF` and `ADDLW` instructions.
 1 = A carry-out from the most significant bit of the result occurred
 Note that a subtraction is executed by adding the two's complement of the second operand. For rotate (`RRCF`, `RLCF`) instructions, this bit is loaded with either the high or low order bit of the source register.
 0 = No carry-out from the most significant bit of the result
 Note: For borrow the polarity is reversed.

6.7 Program Counter Module

The Program Counter (PC) is a 16-bit register. PCL, the low byte of the PC, is mapped in the data memory. PCL is readable and writable just as is any other register. PCH is the high byte of the PC and is not directly addressable. Since PCH is not mapped in data or program memory, an 8-bit register PCLATH (PC high latch) is used as a holding latch for the high byte of the PC. PCLATH is mapped into data memory. The user can read or write PCH through PCLATH.

The 16-bit wide PC is incremented after each instruction fetch during Q1 unless:

- Modified by GOTO, CALL, LCALL, RETURN, RETLW, or RETFIE instruction
- Modified by an interrupt response
- Due to destination write to PCL by an instruction

“Skips” are equivalent to a forced NOP cycle at the skipped address.

Figure 6-11 and Figure 6-12 show the operation of the program counter for various situations.

FIGURE 6-11: PROGRAM COUNTER OPERATION

FIGURE 6-12: PROGRAM COUNTER USING THE CALL AND GOTO INSTRUCTIONS

Using Figure 6-11, the operations of the PC and PCLATH for different instructions are as follows:

- LCALL instructions:**
An 8-bit destination address is provided in the instruction (opcode). PCLATH is unchanged.
PCLATH → PCH
Opcode<7:0> → PCL
- Read instructions on PCL:**
Any instruction that reads PCL.
PCL → data bus → ALU or destination
PCH → PCLATH
- Write instructions on PCL:**
Any instruction that writes to PCL.
8-bit data → data bus → PCL
PCLATH → PCH
- Read-Modify-Write instructions on PCL:**
Any instruction that does a read-write-modify operation on PCL, such as ADDWF PCL.
Read: PCL → data bus → ALU
Write: 8-bit result → data bus → PCL
PCLATH → PCH
- RETURN instruction:**
PCH → PCLATH
Stack<MRU> → PC<15:0>

Using Figure 6-12, the operation of the PC and PCLATH for GOTO and CALL instructions is as follows:

CALL, GOTO instructions:

A 13-bit destination address is provided in the instruction (opcode).

Opcode<12:0> → PC <12:0>

PC<15:13> → PCLATH<7:5>

Opcode<12:8> → PCLATH <4:0>

The read-modify-write only affects the PCL with the result. PCH is loaded with the value in the PCLATH. For example, ADDWF PCL will result in a jump within the current page. If PC = 03F0h, WREG = 30h and PCLATH = 03h before instruction, PC = 0320h after the instruction. To accomplish a true 16-bit computed jump, the user needs to compute the 16-bit destination address, write the high byte to PCLATH and then write the low value to PCL.

The following PC related operations do not change PCLATH:

- LCALL, RETLW, and RETFIE instructions.
- Interrupt vector is forced onto the PC.
- Read-modify-write instructions on PCL (e.g. BSF PCL).

8.0 HARDWARE MULTIPLIER

All PIC17C4X devices except the PIC17C42, have an 8 x 8 hardware multiplier included in the ALU of the device. By making the multiply a hardware operation, it completes in a single instruction cycle. This is an unsigned multiply that gives a 16-bit result. The result is stored into the 16-bit PRODUct register (PRODH:PRODL). The multiplier does not affect any flags in the ALUSTA register.

Making the 8 x 8 multiplier execute in a single cycle gives the following advantages:

- Higher computational throughput
- Reduces code size requirements for multiply algorithms

The performance increase allows the device to be used in applications previously reserved for Digital Signal Processors.

Table 8-1 shows a performance comparison between the PIC17C42 and all other PIC17CXX devices, which have the single cycle hardware multiply.

Example 8-1 shows the sequence to do an 8 x 8 unsigned multiply. Only one instruction is required when one argument of the multiply is already loaded in the WREG register.

Example 8-2 shows the sequence to do an 8 x 8 signed multiply. To account for the sign bits of the arguments, each argument's most significant bit (MSb) is tested and the appropriate subtractions are done.

EXAMPLE 8-1: 8 x 8 MULTIPLY ROUTINE

```
MOVFP    ARG1, WREG
MULWF    ARG2          ; ARG1 * ARG2 ->
                        ; PRODH:PRODL
```

EXAMPLE 8-2: 8 x 8 SIGNED MULTIPLY ROUTINE

```
MOVFP    ARG1, WREG
MULWF    ARG2          ; ARG1 * ARG2 ->
                        ; PRODH:PRODL

BTFSC    ARG2, SB      ; Test Sign Bit
SUBWF    PRODH, F       ; PRODH = PRODH
                        ; - ARG1

MOVFP    ARG2, WREG
BTFSC    ARG1, SB      ; Test Sign Bit
SUBWF    PRODH, F       ; PRODH = PRODH
                        ; - ARG2
```

TABLE 8-1: PERFORMANCE COMPARISON

Routine	Device	Program Memory (Words)	Cycles (Max)	Time	
				@ 25 MHz	@ 33 MHz
8 x 8 unsigned	PIC17C42	13	69	11.04 µs	N/A
	All other PIC17CXX devices	1	1	160 ns	121 ns
8 x 8 signed	PIC17C42	—	—	—	N/A
	All other PIC17CXX devices	6	6	960 ns	727 ns
16 x 16 unsigned	PIC17C42	21	242	38.72 µs	N/A
	All other PIC17CXX devices	24	24	3.84 µs	2.91 µs
16 x 16 signed	PIC17C42	52	254	40.64 µs	N/A
	All other PIC17CXX devices	36	36	5.76 µs	4.36 µs

9.0 I/O PORTS

The PIC17C4X devices have five I/O ports, PORTA through PORTE. PORTB through PORTE have a corresponding Data Direction Register (DDR), which is used to configure the port pins as inputs or outputs. These five ports are made up of 33 I/O pins. Some of these ports pins are multiplexed with alternate functions.

PORTC, PORTD, and PORTE are multiplexed with the system bus. These pins are configured as the system bus when the device's configuration bits are selected to Microprocessor or Extended Microcontroller modes. In the two other microcontroller modes, these pins are general purpose I/O.

PORTA and PORTB are multiplexed with the peripheral features of the device. These peripheral features are:

- Timer modules
- Capture module
- PWM module
- USART/SCI module
- External Interrupt pin

When some of these peripheral modules are turned on, the port pin will automatically configure to the alternate function. The modules that do this are:

- PWM module
- USART/SCI module

When a pin is automatically configured as an output by a peripheral module, the pins data direction (DDR) bit is unknown. After disabling the peripheral module, the user should re-initialize the DDR bit to the desired configuration.

The other peripheral modules (which require an input) must have their data direction bit configured appropriately.

Note: A pin that is a peripheral input, can be configured as an output (DDRx<y> is cleared). The peripheral events will be determined by the action output on the port pin.

9.1 PORTA Register

PORTA is a 6-bit wide latch. PORTA does not have a corresponding Data Direction Register (DDR).

Reading PORTA reads the status of the pins.

The RA1 pin is multiplexed with TMR0 clock input, and RA4 and RA5 are multiplexed with the USART functions. The control of RA4 and RA5 as outputs is automatically configured by the USART module.

9.1.1 USING RA2, RA3 AS OUTPUTS

The RA2 and RA3 pins are open drain outputs. To use the RA2 or the RA3 pin(s) as output(s), simply write to the PORTA register the desired value. A '0' will cause the pin to drive low, while a '1' will cause the pin to float (hi-impedance). An external pull-up resistor should be used to pull the pin high. Writes to PORTA will not affect the other pins.

Note: When using the RA2 or RA3 pin(s) as output(s), read-modify-write instructions (such as BCF, BSF, BTG) on PORTA are not recommended. Such operations read the port pins, do the desired operation, and then write this value to the data latch. This may inadvertently cause the RA2 or RA3 pins to switch from input to output (or vice-versa). It is recommended to use a shadow register for PORTA. Do the bit operations on this shadow register and then move it to PORTA.

FIGURE 9-1: RA0 AND RA1 BLOCK DIAGRAM

Example 9-1 shows the instruction sequence to initialize PORTB. The Bank Select Register (BSR) must be selected to Bank 0 for the port to be initialized.

EXAMPLE 9-1: INITIALIZING PORTB

```
MOVLB 0      ; Select Bank 0
CLRF  PORTB  ; Initialize PORTB by clearing
              ; output data latches
MOVLW 0xCF   ; Value used to initialize
              ; data direction
MOVWF DDRB   ; Set RB<3:0> as inputs
              ; RB<5:4> as outputs
              ; RB<7:6> as inputs
```

TABLE 9-3: PORTB FUNCTIONS

Name	Bit	Buffer Type	Function
RB0/CAP1	bit0	ST	Input/Output or the RB0/CAP1 input pin. Software programmable weak pull-up and interrupt on change features.
RB1/CAP2	bit1	ST	Input/Output or the RB1/CAP2 input pin. Software programmable weak pull-up and interrupt on change features.
RB2/PWM1	bit2	ST	Input/Output or the RB2/PWM1 output pin. Software programmable weak pull-up and interrupt on change features.
RB3/PWM2	bit3	ST	Input/Output or the RB3/PWM2 output pin. Software programmable weak pull-up and interrupt on change features.
RB4/TCLK12	bit4	ST	Input/Output or the external clock input to Timer1 and Timer2. Software programmable weak pull-up and interrupt on change features.
RB5/TCLK3	bit5	ST	Input/Output or the external clock input to Timer3. Software programmable weak pull-up and interrupt on change features.
RB6	bit6	ST	Input/Output pin. Software programmable weak pull-up and interrupt on change features.
RB7	bit7	ST	Input/Output pin. Software programmable weak pull-up and interrupt on change features.

Legend: ST = Schmitt Trigger input.

Legend: x = unknown, u = unchanged.

Note 1: Other (non power-up) resets include: external reset through $\overline{\text{MCLR}}$ and the Watchdog Timer Reset.

14.4.2 MINIMIZING CURRENT CONSUMPTION

To minimize current consumption, all I/O pins should be either at VDD, or VSS, with no external circuitry drawing current from the I/O pin. I/O pins that are hi-impedance inputs should be pulled high or low externally to avoid switching currents caused by floating inputs. The T0CKI input should be at VDD or VSS. The contributions from on-chip pull-ups on PORTB should also be considered, and disabled when possible.

14.5 Code Protection

The code in the program memory can be protected by selecting the microcontroller in code protected mode (PM2:PM0 = '000').

Note: PM2 does not exist on the PIC17C42. To select code protected microcontroller mode, PM1:PM0 = '00'.

In this mode, instructions that are in the on-chip program memory space, can continue to read or write the program memory. An instruction that is executed outside of the internal program memory range will be inhibited from writing to or reading from program memory.

Note: Microchip does not recommend code protecting windowed devices.

If the code protection bit(s) have not been programmed, the on-chip program memory can be read out for verification purposes.

DECF Decrement f

Syntax: [*label*] DECF f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) - 1 \rightarrow (\text{dest})$

Status Affected: OV, C, DC, Z

Encoding:

0000	011d	ffff	ffff
------	------	------	------

Description: Decrement register 'f'. If 'd' is 0 the result is stored in WREG. If 'd' is 1 the result is stored back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Execute	Write to destination

Example: DECF CNT, 1

Before Instruction

CNT = 0x01
Z = 0

After Instruction

CNT = 0x00
Z = 1

DECFSZ Decrement f, skip if 0

Syntax: [*label*] DECFSZ f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) - 1 \rightarrow (\text{dest})$;
skip if result = 0

Status Affected: None

Encoding:

0001	011d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are decremented. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed back in register 'f'.

If the result is 0, the next instruction, which is already fetched, is discarded, and an NOP is executed instead making it a two-cycle instruction.

Words: 1

Cycles: 1(2)

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Execute	Write to destination

Example: HERE DECFSZ CNT, 1
GOTO LOOP

CONTINUE

Before Instruction

PC = Address (HERE)

After Instruction

CNT = CNT - 1
If CNT = 0;
PC = Address (CONTINUE)
If CNT \neq 0;
PC = Address (HERE+1)

PIC17C4X

NOTES:

PIC17C4X Product Identification System

To order or to obtain information, e.g., on pricing or delivery, please use the listed part numbers, and refer to the factory or the listed sales offices.

PART NO. – XX X /XX XXX					Examples	
					a) PIC17C42 – 16/P Commercial Temp., PDIP package, 16 MHz, normal VDD limits	b) PIC17LC44 – 08/PT Commercial Temp., TQFP package, 8MHz, extended VDD limits
				Pattern:		
				Package:		
				Temperature Range:		
				Frequency Range:		
				Device:	c) PIC17C43 – 25I/P Industrial Temp., PDIP package, 25 MHz, normal VDD limits	

Sales and Support

Products supported by a preliminary Data Sheet may possibly have an errata sheet describing minor operational differences and recommended workarounds. To determine if an errata sheet exists for a particular device, please contact one of the following:

1. Your local Microchip sales office (see below)
2. The Microchip Corporate Literature Center U.S. FAX: (602) 786-7277
3. The Microchip's Bulletin Board, via your local CompuServe number (CompuServe membership NOT required).

Please specify which device, revision of silicon and Data Sheet (include Literature #) you are using.

For latest version information and upgrade kits for Microchip Development Tools, please call 1-800-755-2345 or 1-602-786-7302.
