
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	80C51
Core Size	8-Bit
Speed	40MHz
Connectivity	SPI, UART/USART
Peripherals	POR, PWM, WDT
Number of I/O	32
Program Memory Size	16KB (16K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	1.25K x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 3.6V
Data Converters	-
Oscillator Type	External
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Through Hole
Package / Case	40-DIP (0.600", 15.24mm)
Supplier Device Package	40-PDIL
Purchase URL	https://www.e-xfl.com/product-detail/atmel/at89c51rb2-3csul

Block Diagram

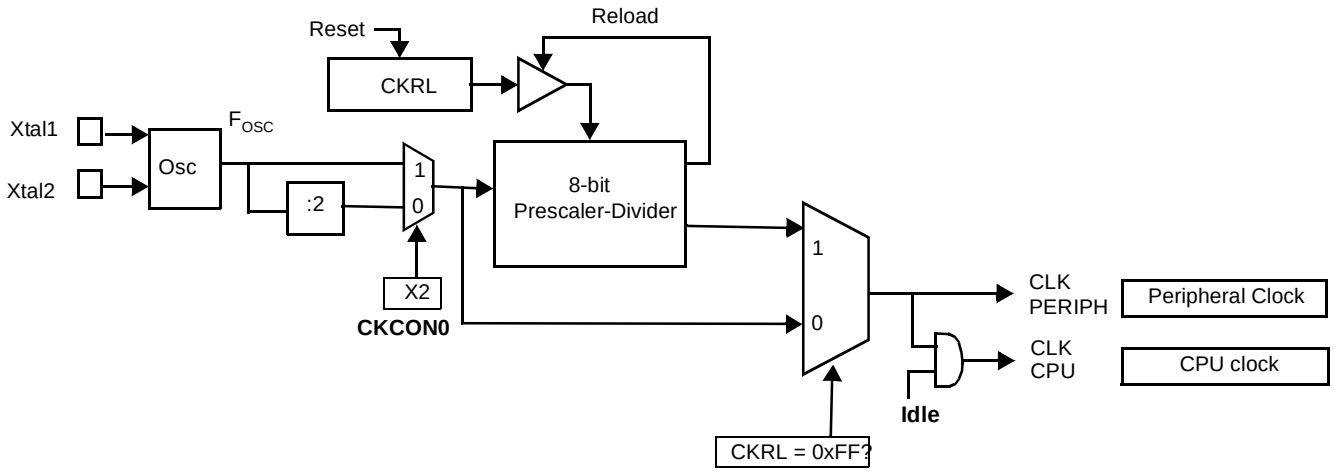
Table 12. Pin Description for 40 - 44 Pin Packages

Mnemonic	Pin Number DIL	LCC	VQFP44 1.4	Type	Name and Function
V_{SS}	20	22	16	I	**Ground**: 0V reference
V_{CC}	40	44	38	I	**Power Supply**: This is the power supply voltage for normal, idle and power-down operation
P0.0 - P0.7	39 - 32	43 - 36	37 - 30	I/O	**Port 0**: Port 0 is an open-drain, bi-directional I/O port. Port 0 pins that have 1s written to them float and can be used as high impedance inputs. Port 0 must be polarized to V_{CC} or V_{SS} in order to prevent any parasitic current consumption. Port 0 is also the multiplexed low-order address and data bus during access to external program and data memory. In this application, it uses strong internal pull-up when emitting 1s. Port 0 also inputs the code Bytes during Flash programming. External pull-ups are required during program verification during which P0 outputs the code Bytes.
P1.0 - P1.7	1 - 8	2 - 9	40 - 44 1 - 3	I/O	**Port 1**: Port 1 is an 8-bit bi-directional I/O port with internal pull-ups. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, Port 1 pins that are externally pulled low will source current because of the internal pull-ups. Port 1 also receives the low-order address Byte during memory programming and verification. Alternate functions for AT89C51RB2/RC2 Port 1 include:
	1	2	40	I/O	**P1.0**: Input/Output
				I/O	**T2 (P1.0):** Timer/Counter 2 external count input/Clockout
	2	3	41	I/O	**P1.1:** Input/Output
				I	**T2EX:** Timer/Counter 2 Reload/Capture/Direction Control
				I	$\overline{\textbf{SS}}$**:** SPI Slave Select
	3	4	42	I/O	**P1.2:** Input/Output
				I	**ECI:** External Clock for the PCA
	4	5	43	I/O	**P1.3:** Input/Output
				I/O	**CEX0:** Capture/Compare External I/O for PCA Module 0
	5	6	44	I/O	**P1.4:** Input/Output
				I/O	**CEX1:** Capture/Compare External I/O for PCA Module 1
	6	7	1	I/O	**P1.5:** Input/Output
				I/O	**CEX2:** Capture/Compare External I/O for PCA Module 2
				I/O	**MISO:** SPI Master Input Slave Output line When SPI is in master mode, MISO receives data from the slave peripheral. When SPI is in slave mode, MISO outputs data to the master controller.
	7	8	2	I/O	**P1.6**: Input/Output
				I/O	**CEX3:** Capture/Compare External I/O for PCA Module 3
				I/O	**SCK:** SPI Serial Clock SCK outputs clock to the slave peripheral
	8	9	3	I/O	**P1.7**: Input/Output:

Functional Block Diagram

Figure 4. Functional Oscillator Block Diagram



Prescaler Divider

- A hardware RESET puts the prescaler divider in the following state:
  - CKRL = FFh: $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSC}/2$ (Standard C51 feature)
- Any value between FFh down to 00h can be written by software into CKRL register in order to divide frequency of the selected oscillator:
  - CKRL = 00h: minimum frequency
    $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSC}/1020$ (Standard Mode)
    $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSC}/510$ (X2 Mode)
  - CKRL = FFh: maximum frequency
    $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSC}/2$ (Standard Mode)
    $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSC}$ (X2 Mode)

$F_{CLK\ CPU}$ and $F_{CLK\ PERIPH}$

In X2 Mode, for CKRL<>0xFF:

$$F_{CPU} = F_{CLKPERIPH} = \frac{F_{OSC}}{2 \times (255 - CKRL)}$$

In X1 Mode, for CKRL<>0xFF then:

$$F_{CPU} = F_{CLKPERIPH} = \frac{F_{OSC}}{4 \times (255 - CKRL)}$$

Table 15. CKCON0 Register

CKCON0 - Clock Control Register (8Fh)

7	6	5	4	3	2	1	0
-	WDX2	PCAX2	SIX2	T2X2	T1X2	T0X2	X2

Bit Number	Bit Mnemonic	Description
7	Reserved	
6	WDX2	**Watchdog Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
5	PCAX2	**Programmable Counter Array Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
4	SIX2	**Enhanced UART Clock (Mode 0 and 2)** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
3	T2X2	**Timer 2 Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
2	T1X2	**Timer 1 Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
1	T0X2	**Timer0 Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
0	X2	**CPU Clock** Cleared to select 12 clock periods per machine cycle (STD, X1 mode) for CPU and all the peripherals. Set to select 6 clock periods per machine cycle (X2 mode) and to enable the individual peripherals'X2' bits. Programmed by hardware after Power-up regarding Hardware Security Byte (HSB), Default setting, X2 is cleared.

Reset Value = 0000 000'HSB. X2'b (see Table 65 "Hardware Security Byte")
Not bit addressable

Programmable Counter Array (PCA)

The PCA provides more timing capabilities with less CPU intervention than the standard timer/counters. Its advantages include reduced software overhead and improved accuracy. The PCA consists of a dedicated timer/counter which serves as the time base for an array of five compare/capture Modules. Its clock input can be programmed to count any one of the following signals:

- Peripheral clock frequency ($F_{CLK\ PERIPH}$) ÷ 6
- Peripheral clock frequency ($F_{CLK\ PERIPH}$) ÷ 2
- Timer 0 overflow
- External input on ECI (P1.2)

Each compare/capture Modules can be programmed in any one of the following modes:

- Rising and/or falling edge capture
- Software timer
- High-speed output
- Pulse width modulator

Module 4 can also be programmed as a watchdog timer (see Section "PCA Watchdog Timer", page 42).

When the compare/capture Modules are programmed in the capture mode, software timer, or high speed output mode, an interrupt can be generated when the Module executes its function. All five Modules plus the PCA timer overflow share one interrupt vector.

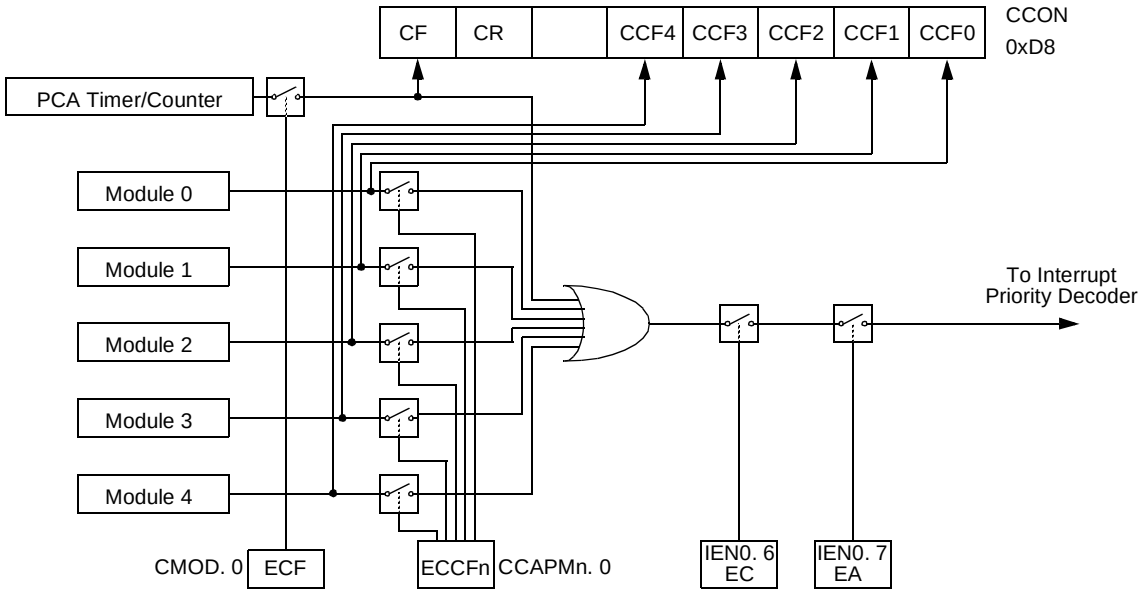
The PCA timer/counter and compare/capture modules share Port 1 for external I/O. These pins are listed below. If one or several bits in the port are not used for the PCA, they can still be used for standard I/O.

PCA Component	External I/O Pin
16-bit Counter	P1.2/ECI
16-bit Module 0	P1.3/CEX0
16-bit Module 1	P1.4/CEX1
16-bit Module 2	P1.5/CEX2
16-bit Module 3	P1.6/CEX3

The PCA timer is a common time base for all five Modules (see Figure 11). The timer count source is determined from the CPS1 and CPS0 bits in the CMOD register (Table 22) and can be programmed to run at:

- 1/6 the peripheral clock frequency ($F_{CLK\ PERIPH}$)
- 1/2 the peripheral clock frequency ($F_{CLK\ PERIPH}$)
- The Timer 0 overflow
- The input on the ECI pin (P1.2)

Figure 12. PCA Interrupt System



PCA Modules: each one of the five compare/capture Modules has six possible functions. It can perform:

- 16-bit Capture, positive-edge triggered
- 16-bit Capture, negative-edge triggered
- 16-bit Capture, both positive and negative-edge triggered
- 16-bit Software Timer
- 16-bit High-speed Output
- 8-bit Pulse Width Modulator

In addition, Module 4 can be used as a Watchdog Timer.

Each Module in the PCA has a special function register associated with it. These registers are: CCAPM0 for Module 0, CCAPM1 for Module 1, etc. (see Table 24). The registers contain the bits that control the mode that each Module will operate in.

- The ECCF bit (CCAPMn. 0 where n = 0, 1, 2, 3, or 4 depending on the Module) enables the CCF flag in the CCON SFR to generate an interrupt when a match or compare occurs in the associated Module.
- PWM (CCAPMn. 1) enables the pulse width modulation mode.
- The TOG bit (CCAPMn. 2) when set causes the CEX output associated with the Module to toggle when there is a match between the PCA counter and the Module's capture/compare register.
- The match bit MAT (CCAPMn. 3) when set will cause the CCFn bit in the CCON register to be set when there is a match between the PCA counter and the Module's capture/compare register.
- The next two bits CAPN (CCAPMn. 4) and CAPP (CCAPMn. 5) determine the edge that a capture input will be active on. The CAPN bit enables the negative edge, and the CAPP bit enables the positive edge. If both bits are set both edges will be enabled and a capture will occur for either transition.
- The last bit in the register ECOM (CCAPMn. 6) when set enables the comparator function.

Table 24 shows the CCAPMn settings for the various PCA functions.

The SADEN byte is selected so that each slave may be addressed separately.
For slave A, bit 0 (the LSB) is a don't-care bit; for slaves B and C, bit 0 is a 1.To communicate with slave A only, the master must send an address where bit 0 is clear (e. g. 1111 0000b).
For slave A, bit 1 is a 1; for slaves B and C, bit 1 is a don't care bit. To communicate with slaves B and C, but not slave A, the master must send an address with bits 0 and 1 both set (e. g. 1111 0011b).
To communicate with slaves A, B and C, the master must send an address with bit 0 set, bit 1 clear, and bit 2 clear (e. g. 1111 0001b).

Broadcast Address

A broadcast address is formed from the logical OR of the SADDR and SADEN registers with zeros defined as don't-care bits, e. g. :

SADDR0101 0110b
SADEN1111 1100b

Broadcast =SADDR OR SADEN1111 111Xb

The use of don't-care bits provides flexibility in defining the broadcast address, however in most applications, a broadcast address is FFh. The following is an example of using broadcast addresses:

Slave A:SADDR1111 0001b
SADEN1111 1010b
Broadcast1111 1X11b,

Slave B:SADDR1111 0011b
SADEN1111 1001b
Broadcast1111 1X11B,

Slave C:SADDR=1111 0011b
SADEN1111 1101b
Broadcast1111 1111b

For slaves A and B, bit 2 is a don't care bit; for slave C, bit 2 is set. To communicate with all of the slaves, the master must send an address FFh. To communicate with slaves A and B, but not slave C, the master can send and address FBh.

Reset Addresses

On reset, the SADDR and SADEN registers are initialized to 00h, i. e. the given and broadcast addresses are XXXX XXXXb (all don't-care bits). This ensures that the serial port will reply to any address, and so, that it is backwards compatible with the 80C51 microcontrollers that do not support automatic address recognition.

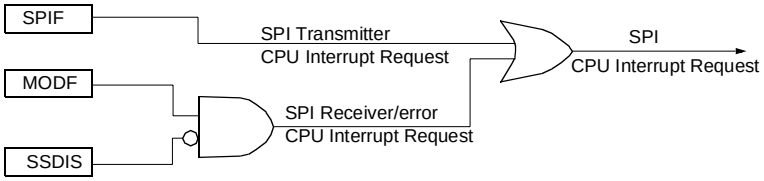
Figure 31. SPI Interrupt Requests Generation



Registers

There are three registers in the Module that provide control, status and data storage functions. These registers are describes in the following paragraphs.

Serial Peripheral Control Register (SPCON)

- The Serial Peripheral Control Register does the following:
- Selects one of the Master clock rates
- Configure the SPI Module as Master or Slave
- Selects serial clock polarity and phase
- Enables the SPI Module
- Frees the SS pin for a general-purpose

Table 56 describes this register and explains the use of each bit

Table 56. SPCON Register

SPCON - Serial Peripheral Control Register (0C3H)

7	6	5	4	3	2	1	0
SPR2	**SPEN**	**SSDIS**	**MSTR**	**CPOL**	**CPHA**	**SPR1**	**SPR0**

Bit Number	Bit Mnemonic	Description
7	SPR2	**Serial Peripheral Rate 2** Bit with SPR1 and SPR0 define the clock rate.
6	SPEN	**Serial Peripheral Enable** Cleared to disable the SPI interface. Set to enable the SPI interface.
5	SSDIS	**$\overline{SS}$ Disable** Cleared to enable $\overline{SS}$ in both Master and Slave modes. Set to disable $\overline{SS}$ in both Master and Slave modes. In Slave mode, this bit has no effect if CPHA ='0'. When SSDIS is set, no MODF interrupt request is generated.
4	MSTR	**Serial Peripheral Master** Cleared to configure the SPI as a Slave. Set to configure the SPI as a Master.
3	CPOL	**Clock Polarity** Cleared to have the SCK set to '0' in idle state. Set to have the SCK set to '1' in idle low.
2	CPHA	**Clock Phase** Cleared to have the data sampled when the SCK leaves the idle state (see CPOL). Set to have the data sampled when the SCK returns to idle state (see CPOL).

Hardware Watchdog Timer

The WDT is intended as a recovery method in situations where the CPU may be subjected to software upset. The WDT consists of a 14-bit counter and the Watchdog Timer Reset (WDTRST) SFR. The WDT is by default disabled from exiting reset. To enable the WDT, user must write 01EH and 0E1H in sequence to the WDTRST, SFR location 0A6H. When WDT is enabled, it will increment every machine cycle while the oscillator is running and there is no way to disable the WDT except through reset (either hardware reset or WDT overflow reset). When WDT overflows, it will drive an output RESET HIGH pulse at the RST-pin.

Using the WDT

To enable the WDT, user must write 01EH and 0E1H in sequence to the WDTRST, SFR location 0A6H. When WDT is enabled, the user needs to service it by writing to 01EH and 0E1H to WDTRST to avoid WDT overflow. The 14-bit counter overflows when it reaches 16383 (3FFFH) and this will reset the device. When WDT is enabled, it will increment every machine cycle while the oscillator is running. This means the user must reset the WDT at least every 16383 machine cycle. To reset the WDT the user must write 01EH and 0E1H to WDTRST. WDTRST is a write only register. The WDT counter cannot be read or written. When WDT overflows, it will generate an output RESET pulse at the RST-pin. The RESET pulse duration is 96 x $T_{CLK\ PERIPH}$, where $T_{CLK\ PERIPH}= 1/F_{CLK\ PERIPH}$. To make the best use of the WDT, it should be serviced in those sections of code that will periodically be executed within the time required to prevent a WDT reset.

To have a more powerful WDT, a 2^7 counter has been added to extend the Time-out capability, ranking from 16 ms to 2 s @ F_{OSCA} = 12 MHz. To manage this feature, see WDTPRG register description, Table 59.

Table 59. WDTRST Register

WDTRST - Watchdog Reset Register (0A6h)

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	-

Reset Value = XXXX XXXXb

Write only, this SFR is used to reset/enable the WDT by writing 01EH then 0E1H in sequence.

Flash Registers and Memory Map

The AT89C51RB2/RC2 Flash memory uses several registers for its management:

- Hardware registers can only be accessed through the parallel programming modes which are handled by the parallel programmer.
- Software registers are in a special page of the Flash memory which can be accessed through the API or with the parallel programming modes. This page, called "Extra Flash Memory", is not in the internal Flash program memory addressing space.

Hardware Register

The only hardware register of the AT89C51RB2/RC2 is called Hardware Security Byte (HSB).

Table 65. Hardware Security Byte (HSB)

7	6	5	4	3	2	1	0
X2	**BLJB**	**-**	**-**	**XRAM**	**LB2**	**LB1**	**LB0**

Bit Number	Bit Mnemonic	Description
7	X2	**X2 Mode** Programmed (‘0’ value) to force X2 mode (6 clocks per instruction) after reset. Unprogrammed (‘1’ Value) to force X1 mode, Standard Mode, after reset (Default).
6	BLJB	**Boot Loader Jump Bit** Unprogrammed (‘1’ value) to start the user’s application on next reset at address 0000h. Programmed (‘0’ value) to start the boot loader at address F800h on next reset (Default).
5	-	**Reserved**
4	-	**Reserved**
3	XRAM	**XRAM Config Bit (only programmable by programmer tools)** Programmed to inhibit XRAM after reset. Unprogrammed, this bit to valid XRAM after reset (Default).
2-0	LB2-0	**User Memory Lock Bits (only programmable by programmer tools)** See Table 66.

Boot Loader Jump Bit (BLJB)

One bit of the HSB, the BLJB bit, is used to force the boot address:

- When this bit is programmed (‘1’ value) the boot address is 0000h.
- When this bit is unprogrammed (‘1’ value) the boot address is F800h. By default, this bit is unprogrammed and the ISP is enabled.

Flash Memory Lock Bits

The three lock bits provide different levels of protection for the on-chip code and data, when programmed as shown in Table 66.

API Call Description

Several Application Program Interface (API) calls are available for use by an application program to permit selective erasing and programming of Flash pages. All calls are made through a common interface, PGM_MTP. The programming functions are selected by setting up the microcontroller's registers before making a call to PGM_MTP at FFF0h. Results are returned in the registers.

When several Bytes have to be programmed, it is highly recommended to use the Atmel API "PROGRAM DATA PAGE" call. Indeed, this API call writes up to 128 Bytes in a single command.

All routines for software access are provided in the C Flash driver available at Atmel's web site.

The API calls description and arguments are shown in Table 74.

Table 74. API Call Summary

Command	R1	A	DPTR0	DPTR1	Returned Value	Command Effect
READ MANUF ID	00h	XXh	0000h	XXh	ACC = Manufacturer Id	Read Manufacturer identifier
READ DEVICE ID1	00h	XXh	0001h	XXh	ACC = Device Id 1	Read Device identifier 1
READ DEVICE ID2	00h	XXh	0002h	XXh	ACC = Device Id 2	Read Device identifier 2
READ DEVICE ID3	00h	XXh	0003h	XXh	ACC = Device Id 3	Read Device identifier 3
ERASE BLOCK	01h	XXh	DPH = 00h	00h	ACC = DPH	Erase block 0
			DPH = 20h			Erase block 1
			DPH = 40h			Erase block 2
PROGRAM DATA BYTE	02h	Vaue to write	Address of byte to program	XXh	ACC = 0: DONE	Program up one data byte in the on-chip flash memory.
PROGRAM SSB	05h	XXh	DPH = 00h DPL = 00h	00h	ACC = SSB value	Set SSB level 1
			DPH = 00h DPL = 01h			Set SSB level 2
			DPH = 00h DPL = 10h			Set SSB level 0
			DPH = 00h DPL = 11h			Set SSB level 1
PROGRAM BSB	06h	New BSB value	0000h	XXh	none	Program boot status byte
PROGRAM SBV	06h	New SBV value	0001h	XXh	none	Program software boot vector
READ SSB	07h	XXh	0000h	XXh	ACC = SSB	Read Software Security Byte
READ BSB	07h	XXh	0001h	XXh	ACC = BSB	Read Boot Status Byte
READ SBV	07h	XXh	0002h	XXh	ACC = SBV	Read Software Boot Vector
PROGRAM DATA PAGE	09h	Number of byte to program	Address of the first byte to program in the Flash memory	Address in XRAM of the first data to program	ACC = 0: DONE	Program up to 128 bytes in user Flash. Remark: number of bytes to program is limited such as the Flash write remains in a single 128 bytes page. Hence, when ACC is 128, valid values of DPL are 00h, or, 80h.
