Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Obsolete
Core Processor	80C51
Core Size	8-Bit
Speed	40MHz
Connectivity	SPI, UART/USART
Peripherals	POR, PWM, WDT
Number of I/O	32
Program Memory Size	16KB (16K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	1.25K x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 3.6V
Data Converters	-
Oscillator Type	External
Operating Temperature	-40°C ~ 85°C
Mounting Type	Surface Mount
Package / Case	44-LQFP
Supplier Device Package	44-VQFP (10x10)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/at89c51rb2-rltil

Block Diagram

Notes: 1. Alternate function of Port 1.
2. Alternate function of Port 3.

SFR Mapping

The Special Function Registers (SFRs) of the AT89C51RB2/RC2 fall into the following categories:

- C51 core registers: ACC, B, DPH, DPL, PSW, SP
- I/O port registers: P0, P1, P2, P3
- Timer registers: T2CON, T2MOD, TCON, TH0, TH1, TH2, TMOD, TL0, TL1, TL2, RCAP2L, RCAP2H
- Serial I/O port registers: SADDR, SADEN, SBUF, SCON
- PCA (Programmable Counter Array) registers: CCON, CCAPMx, CL, CH, CCAPxH, CCAPxL (x: 0 to 4)
- Power and clock control registers: PCON
- Hardware Watchdog Timer registers: WDTRST, WDTPRG
- Interrupt system registers: IEN0, IPL0, IPH0, IEN1, IPL1, IPH1
- Keyboard Interface registers: KBE, KBF, KBLS
- SPI registers: SPCON, SPSTR, SPDAT
- BRG (Baud Rate Generator) registers: BRL, BDRCON
- Flash register: FCON
- Clock Prescaler register: CKRL
- Others: AUXR, AUXR1, CKCON0, CKCON1

Port Types

AT89C51RB2/RC2 I/O ports (P1, P2, P3) implement the quasi-bidirectional output that is common on the 80C51 and most of its derivatives. This output type can be used as both an input and output without the need to reconfigure the port. This is possible because when the port outputs a logic high, it is weakly driven, allowing an external device to pull the pin low. When the pin is pulled low, it is driven strongly and able to sink a fairly large current. These features are somewhat similar to an open drain output except that there are three pull-up transistors in the quasi-bidirectional output that serve different purposes. One of these pull-ups, called the "weak" pull-up, is turned on whenever the port latch for the pin contains a logic 1. The weak pull-up sources a very small current that will pull the pin high if it is left floating. A second pull-up, called the "medium" pull-up, is turned on when the port latch for the pin contains a logic 1 and the pin itself is also at a logic 1 level. This pull-up provides the primary source current for a quasi-bidirectional pin that is outputting a 1. If a pin that has a logic 1 on it is pulled low by an external device, the medium pull-up turns off, and only the weak pull-up remains on. In order to pull the pin low under these conditions, the external device has to sink enough current to overpower the medium pull-up and take the voltage on the port pin below its input threshold.

The third pull-up is referred to as the "strong" pull-up. This pull-up is used to speed up low-to-high transitions on a quasi-bidirectional port pin when the port latch changes from a logic 0 to a logic 1. When this occurs, the strong pull-up turns on for a brief time, two CPU clocks, in order to pull the port pin high quickly. Then it turns off again.

The DPU bit (bit 7 in AUXR register) allows to disable the permanent weak pull up of all ports when latch data is logical 0.

The quasi-bidirectional port configuration is shown in Figure 3.

Figure 3. Quasi-Bidirectional Output

Registers

Table 22. CMOD Register

CMOD – PCA Counter Mode Register (D9h)

7	6	5	4	3	2	1	0
CIDL	**WDTE**	**-**	**-**	**-**	**CPS1**	**CPS0**	**ECF**

Bit Number	Bit Mnemonic	Description
7	CIDL	**Counter Idle Control** Cleared to program the PCA Counter to continue functioning during idle Mode. Set to program PCA to be gated off during idle.
6	WDTE	**Watchdog Timer Enable** Cleared to disable Watchdog Timer function on PCA Module 4. Set to enable Watchdog Timer function on PCA Module 4.
5	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
4	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
3	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
2	CPS1	**PCA Count Pulse Select** CPS1 CPS0 Selected PCA input 0 0 Internal clock $F_{CLK\ PERIPH}/6$ 0 1 Internal clock $F_{LK\ PERIPH}/2$ 1 0 Timer 0 Overflow 1 1 External clock at ECI/P1.2 pin (max rate = fCLK PERIPH/ 4)
1	CPS0	
0	ECF	**PCA Enable Counter Overflow Interrupt** Cleared to disable CF bit in CCON to inhibit an interrupt. Set to enable CF bit in CCON to generate an interrupt.

Reset Value = 00XX X000b
Not bit addressable

The CMOD register includes three additional bits associated with the PCA.

- The CIDL bit which allows the PCA to stop during idle mode.
- The WDTE bit which enables or disables the watchdog function on Module 4.
- The ECF bit which when set causes an interrupt and the PCA overflow flag CF (in the CCON SFR) to be set when the PCA timer overflows.

The CCON register contains the run control bit for the PCA and the flags for the PCA timer (CF) and each Module (see Table 23).

- Bit CR (CCON. 6) must be set by software to run the PCA. The PCA is shut off by clearing this bit.
- Bit CF: The CF bit (CCON. 7) is set when the PCA counter overflows and an interrupt will be generated if the ECF bit in the CMOD register is set. The CF bit can only be cleared by software.
- Bits 0 through 4 are the flags for the Modules (bit 0 for Module 0, bit 1 for Module 1, etc.) and are set by hardware when either a match or a capture occurs. These flags also can only be cleared by software.

Table 24. CCAPMn Registers (n = 0-4)

CCAPM0 – PCA Module 0 Compare/Capture Control Register (0DAh)

CCAPM1 – PCA Module 1 Compare/Capture Control Register (0DBh)

CCAPM2 – PCA Module 2 Compare/Capture Control Register (0DCh)

CCAPM3 – PCA Module 3 Compare/Capture Control Register (0DDh)

CCAPM4 – PCA Module 4 Compare/Capture Control Register (0DEh)

7	6	5	4	3	2	1	0
-	ECOMn	CAPPn	CAPNn	MATn	TOGn	PWMn	ECCFn

Bit Number	Bit Mnemonic	Description
7	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
6	ECOMn	**Enable Comparator** Cleared to disable the comparator function. Set to enable the comparator function.
5	CAPPn	**Capture Positive** Cleared to disable positive edge capture. Set to enable positive edge capture.
4	CAPNn	**Capture Negative** Cleared to disable negative edge capture. Set to enable negative edge capture.
3	MATn	**Match** When MATn = 1, a match of the PCA counter with this Module's compare/capture register causes the CCFn bit in CCON to be set, flagging an interrupt.
2	TOGn	**Toggle** When TOGn = 1, a match of the PCA counter with this Module's compare/capture register causes theCEXn pin to toggle.
1	PWMn	**Pulse Width Modulation Mode** Cleared to disable the CEXn pin to be used as a pulse width modulated output. Set to enable the CEXn pin to be used as a pulse width modulated output.
0	CCF0	**Enable CCF Interrupt** Cleared to disable compare/capture flag CCFn in the CCON register to generate an interrupt. Set to enable compare/capture flag CCFn in the CCON register to generate an interrupt.

Reset Value = X000 0000b
Not bit addressable

Table 25. PCA Module Modes (CCAPMn Registers)

ECOMn	CAPPn	CAPNn	MATn	TOGn	PWMm	ECCFn	Module Function
0	0	0	0	0	0	0	No Operation
X	1	0	0	0	0	X	16-bit capture by a positive-edge trigger on CEXn
X	0	1	0	0	0	X	16-bit capture by a negative trigger on CEXn
X	1	1	0	0	0	X	16-bit capture by a transition on CEXn
1	0	0	1	0	0	X	16-bit Software Timer/Compare mode.
1	0	0	1	1	0	X	16-bit High-speed Output
1	0	0	0	0	1	0	8-bit PWM
1	0	0	1	X	0	X	Watchdog Timer (Module 4 only)

There are two additional registers associated with each of the PCA Modules. They are CCAPnH and CCAPnL and these are the registers that store the 16-bit count when a capture occurs or a compare should occur. When a Module is used in the PWM mode these registers are used to control the duty cycle of the output (see Table 26 and Table 27).

Table 26. CCAPnH Registers (n = 0-4)

CCAP0H – PCA Module 0 Compare/Capture Control Register High (0FAh)

CCAP1H – PCA Module 1 Compare/Capture Control Register High (0FBh)

CCAP2H – PCA Module 2 Compare/Capture Control Register High (0FCh)

CCAP3H – PCA Module 3 Compare/Capture Control Register High (0FDh)

CCAP4H – PCA Module 4 Compare/Capture Control Register High (0FEh)

Baud Rate Selection for UART for Mode 1 and 3

The Baud Rate Generator for transmit and receive clocks can be selected separately via the T2CON and BDRCON registers.

Figure 20. Baud Rate Selection

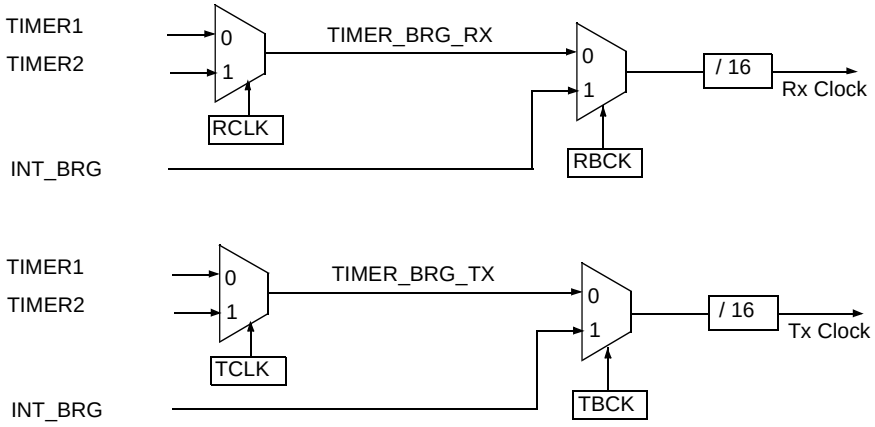

Table 40. T2CON Register

T2CON - Timer 2 Control Register (C8h)

7	6	5	4	3	2	1	0
TF2	EXF2	RCLK	TCLK	EXEN2	TR2	C/T2#	CP/RL2#

Bit Number	Bit Mnemonic	Description
7	TF2	**Timer 2 overflow Flag** Must be cleared by software. Set by hardware on timer 2 overflow, if RCLK = 0 and TCLK = 0.
6	EXF2	**Timer 2 External Flag** Set when a capture or a reload is caused by a negative transition on T2EX pin if EXEN2=1. When set, causes the CPU to vector to timer 2 interrupt routine when timer 2 interrupt is enabled. Must be cleared by software. EXF2 doesn't cause an interrupt in Up/down counter mode (DCEN = 1)
5	RCLK	**Receive Clock bit for UART** Cleared to use timer 1 overflow as receive clock for serial port in mode 1 or 3. Set to use timer 2 overflow as receive clock for serial port in mode 1 or 3.
4	TCLK	**Transmit Clock bit for UART** Cleared to use timer 1 overflow as transmit clock for serial port in mode 1 or 3. Set to use timer 2 overflow as transmit clock for serial port in mode 1 or 3.
3	EXEN2	**Timer 2 External Enable bit** Cleared to ignore events on T2EX pin for timer 2 operation. Set to cause a capture or reload when a negative transition on T2EX pin is detected, if timer 2 is not used to clock the serial port.
2	TR2	**Timer 2 Run control bit** Cleared to turn off timer 2. Set to turn on timer 2.
1	C/T2#	**Timer/Counter 2 select bit** Cleared for timer operation (input from internal clock system: $F_{CLK\ PERIPH}$). Set for counter operation (input from T2 input pin, falling edge trigger). Must be 0 for clock out mode.
0	CP/RL2#	**Timer 2 Capture/Reload bit** If RCLK=1 or TCLK=1, CP/RL2# is ignored and timer is forced to auto-reload on timer 2 overflow. Cleared to auto-reload on timer 2 overflows or negative transitions on T2EX pin if EXEN2=1. Set to capture on negative transitions on T2EX pin if EXEN2=1.

Reset Value = 0000 0000b
Bit addressable

A low-priority interrupt can be interrupted by a high-priority interrupt, but not by another low-priority interrupt. A high-priority interrupt can't be interrupted by any other interrupt source.

Table 43. Priority Level Bit Values

IPH. x	IPL. x	Interrupt Level Priority
0	0	0 (Lowest)
0	1	1
1	0	2
1	1	3 (Highest)

If two interrupt requests of different priority levels are received simultaneously, the request of higher-priority level is serviced. If interrupt requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence.

Keyboard Interface

The AT89C51RB2/RC2 implements a keyboard interface allowing the connection of a 8 x n matrix keyboard. It is based on 8 inputs with programmable interrupt capability on both high or low level. These inputs are available as alternate function of P1 and allow to exit from idle and power-down modes.

The keyboard interfaces with the C51 core through 3 special function registers: KBLS, the Keyboard Level Selection register (Table 53), KBE, the Keyboard interrupt Enable register (Table 52), and KBF, the Keyboard Flag register (Table 51).

Interrupt

The keyboard inputs are considered as 8 independent interrupt sources sharing the same interrupt vector. An interrupt enable bit (KBD in IEN1) allows global enable or disable of the keyboard interrupt (see Figure 23). As detailed in Figure 24 each keyboard input has the capability to detect a programmable level according to KBLS. x bit value. Level detection is then reported in interrupt flags KBF. x that can be masked by software using KBE. x bits.

This structure allows keyboard arrangement from 1 by n to 8 by n matrix and allow usage of P1 inputs for other purpose.

Figure 23. Keyboard Interface Block Diagram

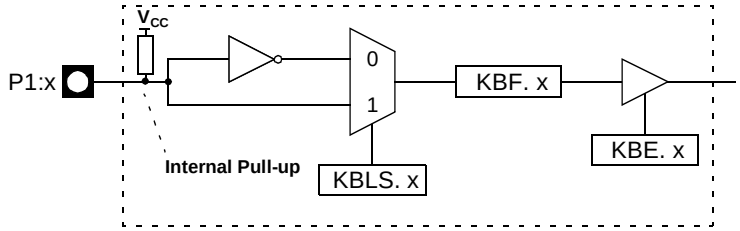

Figure 24. Keyboard Input Circuitry

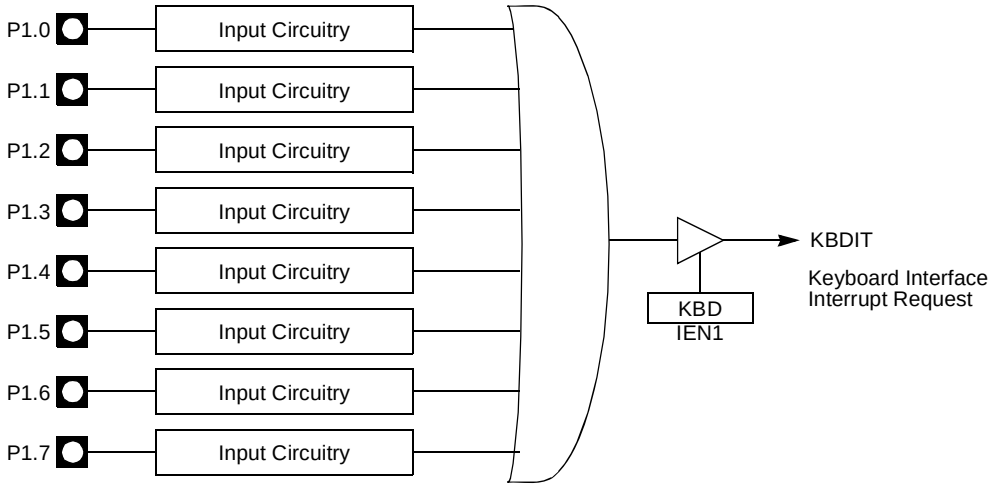


Power Reduction Mode

P1 inputs allow exit from idle and power down modes as detailed in Section “Power-down Mode”, page 82.

Serial Port Interface (SPI)

The Serial Peripheral Interface Module (SPI) allows full-duplex, synchronous, serial communication between the MCU and peripheral devices, including other MCUs.

Features

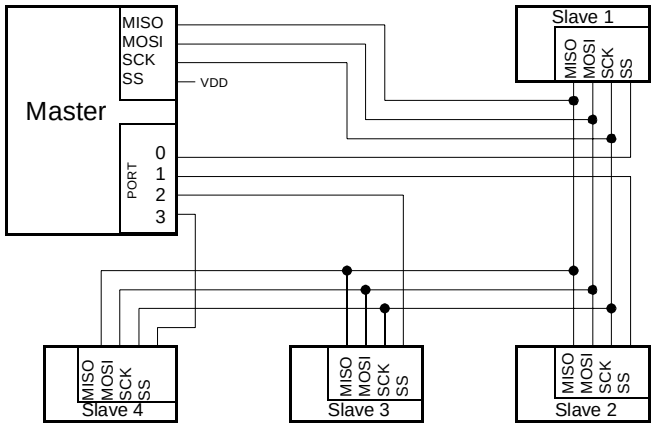
Features of the SPI Module include the following:

- Full-duplex, three-wire synchronous transfers
- Master or Slave operation
- Eight programmable Master clock rates
- Serial clock with programmable polarity and phase
- Master Mode fault error flag with MCU interrupt capability
- Write collision flag protection

Signal Description

Figure 25 shows a typical SPI bus configuration using one Master controller and many Slave peripherals. The bus is made of three wires connecting all the devices.

Figure 25. SPI Master/Slaves Interconnection



The Master device selects the individual Slave devices by using four pins of a parallel port to control the four $\overline{SS}$ pins of the Slave devices.

Master Output Slave Input (MOSI)

This 1-bit signal is directly connected between the Master Device and a Slave Device. The MOSI line is used to transfer data in series from the Master to the Slave. Therefore, it is an output signal from the Master, and an input signal to a Slave. A Byte (8-bit word) is transmitted most significant bit (MSB) first, least significant bit (LSB) last.

Master Input Slave Output (MISO)

This 1-bit signal is directly connected between the Slave Device and a Master Device. The MISO line is used to transfer data in series from the Slave to the Master. Therefore, it is an output signal from the Slave, and an input signal to the Master. A Byte (8-bit word) is transmitted most significant bit (MSB) first, least significant bit (LSB) last.

SPI Serial Clock (SCK)

This signal is used to synchronize the data movement both in and out of the devices through their MOSI and MISO lines. It is driven by the Master for eight clock cycles which allows to exchange one Byte on the serial lines.

Slave Select ($\overline{SS}$)

Each Slave peripheral is selected by one Slave Select pin ($\overline{SS}$). This signal must stay low for any message for a Slave. It is obvious that only one Master ($\overline{SS}$ high level) can

ONCE™ Mode (ON Chip Emulation)

The ONCE mode facilitates testing and debugging of systems using AT89C51RB2/RC2 without removing the circuit from the board. The ONCE mode is invoked by driving certain pins of the AT89C51RB2/RC2; the following sequence must be exercised:

- Pull ALE low while the device is in reset (RST high) and $\overline{\text{PSEN}}$ is high.
- Hold ALE low as RST is deactivated.

While the AT89C51RB2/RC2 is in ONCE mode, an emulator or test CPU can be used to drive the circuit. Table 61 shows the status of the port pins during ONCE mode.

Normal operation is restored when normal reset is applied.

Table 61. External Pin Status during ONCE Mode

ALE	PSEN	Port 0	Port 1	Port 2	Port 3	XTAL1/2
Weak pull-up	Weak pull-up	Float	Weak pull-up	Weak pull-up	Weak pull-up	Active

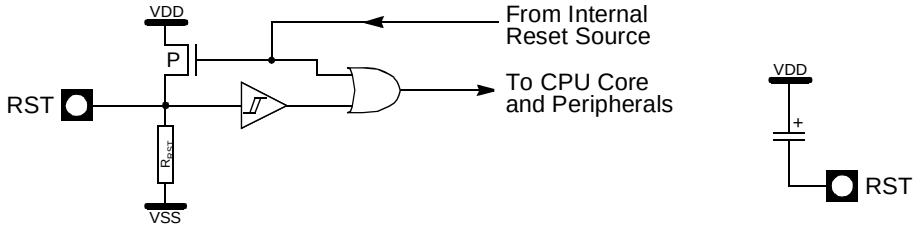
Power Management

Two power reduction modes are implemented in the AT89C51RB2/RC2: the Idle mode and the Power-down mode. These modes are detailed in the following sections. In addition to these power reduction modes, the clocks of the core and peripherals can be dynamically divided by 2 using the X2 mode detailed in Section “X2 Feature”.

Reset

In order to start-up (cold reset) or to restart (warm reset) properly the microcontroller, an high level has to be applied on the RST pin. A bad level leads to a wrong initialization of the internal registers like SFRs, Program Counter… and to unpredictable behavior of the microcontroller. A proper device reset initializes the AT89C51RB2/RC2 and vectors the CPU to address 0000h. RST input has a pull-down resistor allowing power-on reset by simply connecting an external capacitor to V_{DD} as shown in Figure 32. A warm reset can be applied either directly on the RST pin or indirectly by an internal reset source such as the watchdog timer. Resistor value and input characteristics are discussed in the Section “DC Characteristics” of the AT89C51RB2/RC2 datasheet.

Figure 32. Reset Circuitry and Power-On Reset



RST input circuitry

Power-on Reset

Cold Reset

2 conditions are required before enabling a CPU start-up:

- V_{DD} must reach the specified V_{DD} range
- The level on X1 input pin must be outside the specification (V_{IH}, V_{IL})

If one of these 2 conditions are not met, the microcontroller does not start correctly and can execute an instruction fetch from anywhere in the program space. An active level applied on the RST pin must be maintained till both of the above conditions are met. A reset is active when the level V_{IH1} is reached and when the pulse width covers the period of time where V_{DD} and the oscillator are not stabilized. 2 parameters have to be taken into account to determine the reset pulse width:

- V_{DD} rise time,
- Oscillator startup time.

To determine the capacitor value to implement, the highest value of these 2 parameters has to be chosen. Table 1 gives some capacitor values examples for a minimum R_{RST} of 50 KΩ and different oscillator startup and V_{DD} rise times.

Reduced EMI Mode

The ALE signal is used to demultiplex address and data buses on port 0 when used with external program or data memory. Nevertheless, during internal code execution, ALE signal is still generated. In order to reduce EMI, ALE signal can be disabled by setting AO bit.

The AO bit is located in AUXR register at bit location 0.As soon as AO is set, ALE is no longer output but remains active during MOVX and MOVC instructions and external fetches. During ALE disabling, ALE pin is weakly pulled high.

Table 64. AUXR Register

AUXR - Auxiliary Register (8Eh)

7	6	5	4	3	2	1	0
DPU	**-**	**M0**	**-**	**XRS1**	**XRS0**	**EXTRAM**	**AO**

Bit Number	Bit Mnemonic	Description
7	DPU	**Disable Weak Pull-up** Cleared to activate the permanent weak pull up when latch data is logic 1 Set to disactive the weak pull-up.
6	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
5	M0	**Pulse Length** Cleared to stretch MOVX control: the $\overline{RD}$ and the $\overline{WR}$ pulse length is 6 clock periods (default). Set to stretch MOVX control: the $\overline{RD}$ and the $\overline{WR}$ pulse length is 30 clock periods.
4	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
3	XRS1	**XRAM Size** XRS1 XRS0 XRAM size 0 0 256 Bytes (default) 0 1 512 Bytes 1 0 768 Bytes 1 1 1024 Bytes
2	XRS0	
1	EXTRAM	**EXTRAM Bit** Cleared to access internal XRAM using movx @ $\overline{Ri}$ @ DPTR. Set to access external memory. Programmed by hardware after Power-up regarding Hardware Security Byte (HSB), default setting, XRAM selected.
0	AO	**ALE Output Bit** Cleared, ALE is emitted at a constant rate of 1/6 the oscillator frequency (or 1/3 if X2 mode is used). (default) Set, ALE is active only during a MOVX or MOVC instruction is used.

Table 66. Program Lock Bits

Program Lock Bits				
Security Level	**LB0**	**LB1**	**LB2**	**Protection Description**
1	U	U	U	No program lock features enabled.
2	P	U	U	MOVC instruction executed from external program memory is disabled from fetching code Bytes from internal memory, $\overline{EA}$ is sampled and latched on reset, and further parallel programming of the Flash is disabled. ISP and software programming with API are still allowed.
3	X	P	U	Same as 2, also verify through parallel programming interface is disabled.
4	X	X	P	Same as 3, also external execution is disabled. (Default)

Note: U: unprogrammed or "one" level.
P: programmed or "zero" level.
X: don't care
WARNING: Security level '2' and '3' should only be programmed after Flash and code verification.

These security bits protect the code access through the parallel programming interface. They are set by default to level 4. The code access through the ISP is still possible and is controlled by the "software security bits" which are stored in the extra Flash memory accessed by the ISP firmware.

To load a new application with the parallel programmer, a chip erase must first be done. This will set the HSB in its inactive state and will erase the Flash memory. The part reference can always be read using Flash parallel programming modes.

Default Values

The default value of the HSB provides parts ready to be programmed with ISP:

- BLJB: Programmed force ISP operation.
- X2: Unprogrammed to force X1 mode (Standard Mode).
- XRAM: Unprogrammed to valid XRAM
- LB2-0: Security level four to protect the code from a parallel access with maximum security.

Software Registers

Several registers are used, in factory and by parallel programmers, to make copies of hardware registers contents. These values are used by Atmel ISP.

These registers are in the "Extra Flash Memory" part of the Flash memory. This block is also called "XAF" or eXtra Array Flash. They are accessed in the following ways:

- Commands issued by the parallel memory programmer.
- Commands issued by the ISP software.
- Calls of API issued by the application software.

Several software registers are described in Table 67.

ISP Protocol Description

Physical Layer

The UART used to transmit information has the following configuration:

- Character: 8-bit data
- Parity: none
- Stop: 1 bit
- Flow control: none
- Baud rate: autobaud is performed by the bootloader to compute the baud rate choosen by the host.

Frame Description

The Serial Protocol is based on the Intel Hex-type records.

Intel Hex records consist of ASCII characters used to represent hexadecimal values and are summarized below.

Table 70. Intel Hex Type Frame

Record Mark ':'	Reclen	Load Offset	Record Type	Data or Info	Checksum
1 byte	1 byte	2 bytes	1 bytes	n byte	1 byte

- Record Mark:
  - Record Mark is the start of frame. This field must contain ':'.
- Reclen:
  - Reclen specifies the number of Bytes of information or data which follows the Record Type field of the record.
- Load Offset:
  - Load Offset specifies the 16-bit starting load offset of the data Bytes, therefore this field is used only for
  - Data Program Record (see Section "ISP Commands Summary").
- Record Type:
  - Record Type specifies the command type. This field is used to interpret the remaining information within the frame. The encoding for all the current record types is described in Section "ISP Commands Summary".
- Data/Info:
  - Data/Info is a variable length field. It consists of zero or more Bytes encoded as pairs of hexadecimal digits. The meaning of data depends on the Record Type.
- Checksum:
  - The two's complement of the 8-bit Bytes that result from converting each pair of ASCII hexadecimal digits to one Byte of binary, and including the Reclen field to and including the last Byte of the Data/Info field. Therefore, the sum of all the ASCII pairs in a record after converting to binary, from the Reclen field to and including the Checksum field, is zero.

Table 74. API Call Summary (Continued)

Command	R1	A	DPTR0	DPTR1	Returned Value	Command Effect
PROGRAM X2 FUSE	0Ah	Fuse value 00h or 01h	0008h	XXh	none	Program X2 fuse bit with ACC
