
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	80C51
Core Size	8-Bit
Speed	60MHz
Connectivity	SPI, UART/USART
Peripherals	POR, PWM, WDT
Number of I/O	32
Program Memory Size	16KB (16K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	1.25K x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 5.5V
Data Converters	-
Oscillator Type	External
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	44-LCC (J-Lead)
Supplier Device Package	44-PLCC (16.6x16.6)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/at89c51rb2-slsum

Table 12. Pin Description for 40 - 44 Pin Packages

Mnemonic	Pin Number DIL	LCC	VQFP44 1.4	Type	Name and Function
V_{SS}	20	22	16	I	**Ground**: 0V reference
V_{CC}	40	44	38	I	**Power Supply**: This is the power supply voltage for normal, idle and power-down operation
P0.0 - P0.7	39 - 32	43 - 36	37 - 30	I/O	**Port 0**: Port 0 is an open-drain, bi-directional I/O port. Port 0 pins that have 1s written to them float and can be used as high impedance inputs. Port 0 must be polarized to V_{CC} or V_{SS} in order to prevent any parasitic current consumption. Port 0 is also the multiplexed low-order address and data bus during access to external program and data memory. In this application, it uses strong internal pull-up when emitting 1s. Port 0 also inputs the code Bytes during Flash programming. External pull-ups are required during program verification during which P0 outputs the code Bytes.
P1.0 - P1.7	1 - 8	2 - 9	40 - 44 1 - 3	I/O	**Port 1**: Port 1 is an 8-bit bi-directional I/O port with internal pull-ups. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, Port 1 pins that are externally pulled low will source current because of the internal pull-ups. Port 1 also receives the low-order address Byte during memory programming and verification. Alternate functions for AT89C51RB2/RC2 Port 1 include:
	1	2	40	I/O	**P1.0**: Input/Output
				I/O	**T2 (P1.0):** Timer/Counter 2 external count input/Clockout
	2	3	41	I/O	**P1.1:** Input/Output
				I	**T2EX:** Timer/Counter 2 Reload/Capture/Direction Control
				I	$\overline{\textbf{SS}}$**:** SPI Slave Select
	3	4	42	I/O	**P1.2:** Input/Output
				I	**ECI:** External Clock for the PCA
	4	5	43	I/O	**P1.3:** Input/Output
				I/O	**CEX0:** Capture/Compare External I/O for PCA Module 0
	5	6	44	I/O	**P1.4:** Input/Output
				I/O	**CEX1:** Capture/Compare External I/O for PCA Module 1
	6	7	1	I/O	**P1.5:** Input/Output
				I/O	**CEX2:** Capture/Compare External I/O for PCA Module 2
				I/O	**MISO:** SPI Master Input Slave Output line When SPI is in master mode, MISO receives data from the slave peripheral. When SPI is in slave mode, MISO outputs data to the master controller.
	7	8	2	I/O	**P1.6**: Input/Output
				I/O	**CEX3:** Capture/Compare External I/O for PCA Module 3
				I/O	**SCK:** SPI Serial Clock SCK outputs clock to the slave peripheral
	8	9	3	I/O	**P1.7**: Input/Output:

Table 16. CKCON1 Register

CKCON1 - Clock Control Register (AFh)

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	SPIX2

Bit Number	Bit Mnemonic	Description
7	-	**Reserved**
6	-	**Reserved**
5	-	**Reserved**
4	-	**Reserved**
3	-	**Reserved**
2	-	**Reserved**
1	-	**Reserved**
0	SPIX2	**SPI** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Clear to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.

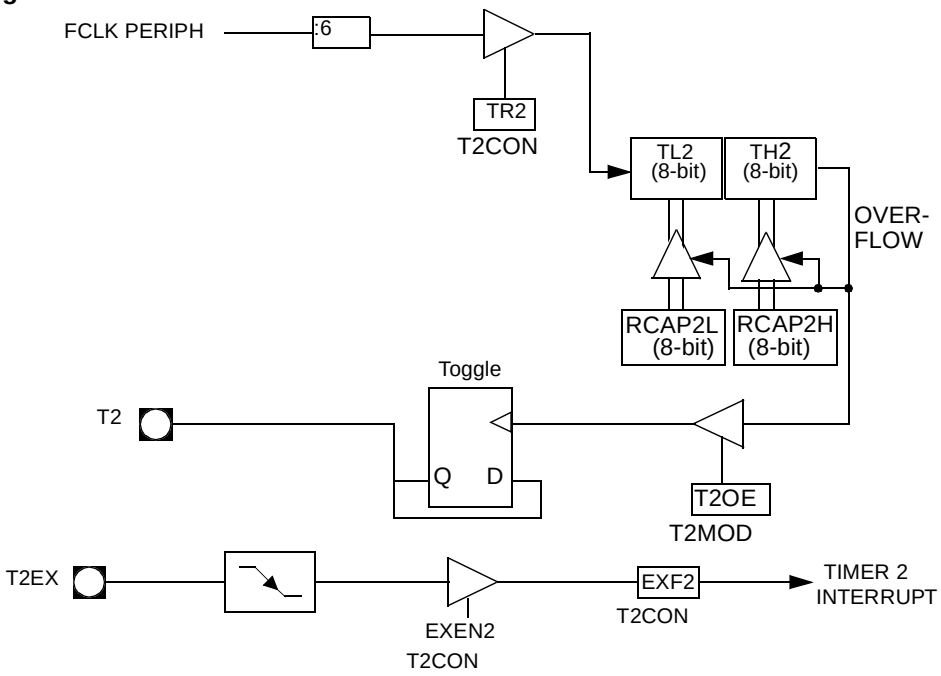
Reset Value = XXXX XXX0b
Not bit addressable

- Instructions that use indirect addressing access the Upper 128 Bytes of data RAM. For example: MOV @R0, # data where R0 contains 0A0h, accesses the data Byte at address 0A0h, rather than P2 (whose address is 0A0h).
- The XRAM Bytes can be accessed by indirect addressing, with EXTRAM bit cleared and MOVX instructions. This part of memory that is physically located on-chip, logically occupies the first Bytes of external data memory. The bits XRS0 and XRS1 are used to hide a part of the available XRAM as explained in Table 18. This can be useful if external peripherals are mapped at addresses already used by the internal XRAM.
- With EXTRAM = 0, the XRAM is indirectly addressed, using the MOVX instruction in combination with any of the registers R0, R1 of the selected bank or DPTR. An access to XRAM will not affect ports P0, P2, P3.6 (WR) and P3.7 (RD). For example, with EXTRAM = 0, MOVX @R0, # data where R0 contains 0A0H, accesses the XRAM at address 0A0H rather than external memory. An access to external data memory locations higher than the accessible size of the XRAM will be performed with the MOVX DPTR instructions in the same way as in the standard 80C51, with P0 and P2 as data/address busses, and P3.6 and P3.7 as write and read timing signals. Accesses to XRAM above 0FFH can only be done by the use of DPTR.
- With EXTRAM = 1, MOVX @RI and MOVX @DPTR will be similar to the standard 80C51. MOVX @ Ri will provide an eight-bit address multiplexed with data on Port0 and any output port pins can be used to output higher order address bits. This is to provide the external paging capability. MOVX @DPTR will generate a sixteen-bit address. Port2 outputs the high-order eight address bits (the contents of DPH) while Port0 multiplexes the low-order eight address bits (DPL) with data. MOVX @ RI and MOVX @DPTR will generate either read or write signals on P3.6 ($\overline{WR}$) and P3.7 ($\overline{RD}$).

The stack pointer (SP) may be located anywhere in the 256 Bytes RAM (lower and upper RAM) internal data memory. The stack may not be located in the XRAM.

The M0 bit allows to stretch the XRAM timings; if M0 is set, the read and write pulses are extended from 6 to 30 clock periods. This is useful to access external slow peripherals.

Figure 10. Clock-Out Mode C/$\overline{T2}$ = 0



Programmable Counter Array (PCA)

The PCA provides more timing capabilities with less CPU intervention than the standard timer/counters. Its advantages include reduced software overhead and improved accuracy. The PCA consists of a dedicated timer/counter which serves as the time base for an array of five compare/capture Modules. Its clock input can be programmed to count any one of the following signals:

- Peripheral clock frequency ($F_{CLK\ PERIPH}$) ÷ 6
- Peripheral clock frequency ($F_{CLK\ PERIPH}$) ÷ 2
- Timer 0 overflow
- External input on ECI (P1.2)

Each compare/capture Modules can be programmed in any one of the following modes:

- Rising and/or falling edge capture
- Software timer
- High-speed output
- Pulse width modulator

Module 4 can also be programmed as a watchdog timer (see Section "PCA Watchdog Timer", page 42).

When the compare/capture Modules are programmed in the capture mode, software timer, or high speed output mode, an interrupt can be generated when the Module executes its function. All five Modules plus the PCA timer overflow share one interrupt vector.

The PCA timer/counter and compare/capture modules share Port 1 for external I/O. These pins are listed below. If one or several bits in the port are not used for the PCA, they can still be used for standard I/O.

PCA Component	External I/O Pin
16-bit Counter	P1.2/ECI
16-bit Module 0	P1.3/CEX0
16-bit Module 1	P1.4/CEX1
16-bit Module 2	P1.5/CEX2
16-bit Module 3	P1.6/CEX3

The PCA timer is a common time base for all five Modules (see Figure 11). The timer count source is determined from the CPS1 and CPS0 bits in the CMOD register (Table 22) and can be programmed to run at:

- 1/6 the peripheral clock frequency ($F_{CLK\ PERIPH}$)
- 1/2 the peripheral clock frequency ($F_{CLK\ PERIPH}$)
- The Timer 0 overflow
- The input on the ECI pin (P1.2)

Not bit addressable

PCA Capture Mode

To use one of the PCA Modules in the capture mode either one or both of the CCAPM bits CAPN and CAPP for that Module must be set. The external CEX input for the Module (on port 1) is sampled for a transition. When a valid transition occurs the PCA hardware loads the value of the PCA counter registers (CH and CL) into the Module's capture registers (CCAPnL and CCAPnH). If the CCFn bit for the Module in the CCON SFR and the ECCFn bit in the CCAPMn SFR are set then an interrupt will be generated (see Figure 13).

Figure 13. PCA Capture Mode

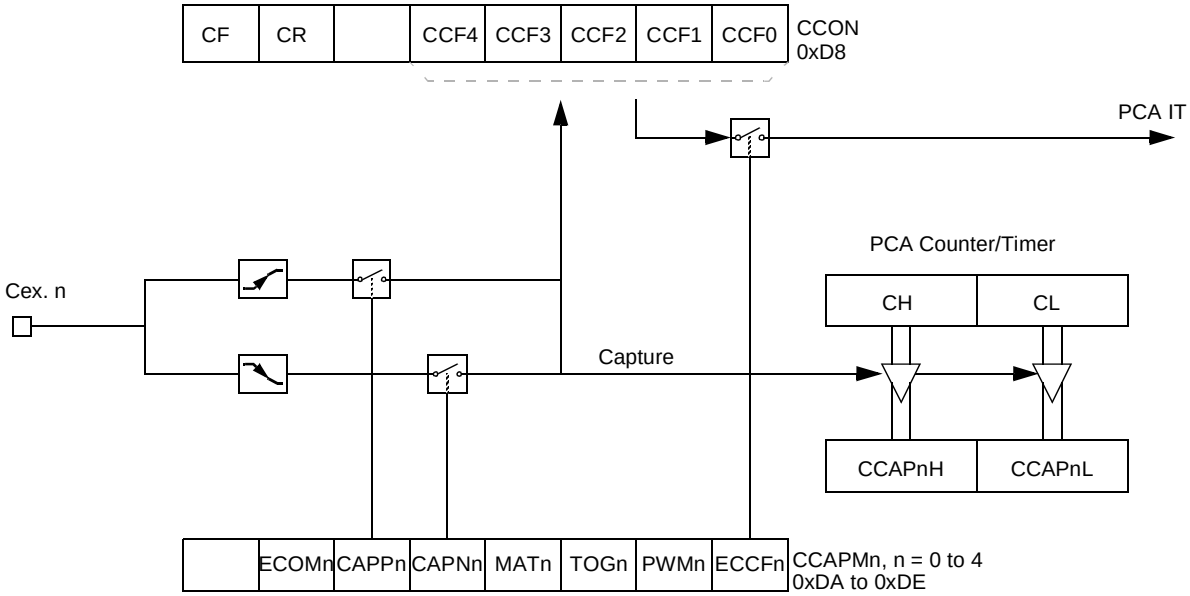

Figure 19. UART Timings in Modes 2 and 3

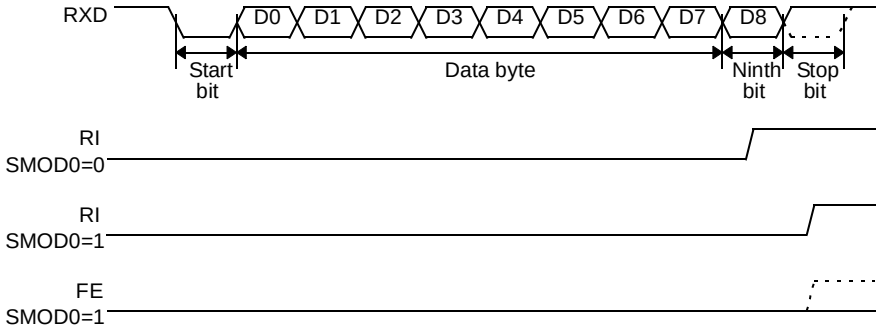


Automatic Address Recognition

The automatic address recognition feature is enabled when the multiprocessor communication feature is enabled (SM2 bit in SCON register is set).

Implemented in hardware, automatic address recognition enhances the multiprocessor communication feature by allowing the serial port to examine the address of each incoming command frame. Only when the serial port recognizes its own address, the receiver sets RI bit in SCON register to generate an interrupt. This ensures that the CPU is not interrupted by command frames addressed to other devices.

If desired, the user may enable the automatic address recognition feature in mode 1.In this configuration, the stop bit takes the place of the ninth data bit. Bit RI is set only when the received command frame address matches the device's address and is terminated by a valid stop bit.

To support automatic address recognition, a device is identified by a given address and a broadcast address.

Note: The multiprocessor communication and automatic address recognition features cannot be enabled in mode 0 (i. e. setting SM2 bit in SCON register in mode 0 has no effect).

Given Address

Each device has an individual address that is specified in SADDR register; the SADEN register is a mask byte that contains don't-care bits (defined by zeros) to form the device's given address. The don't-care bits provide the flexibility to address one or more slaves at a time. The following example illustrates how a given address is formed.

To address a device by its individual address, the SADEN mask byte must be `1111 1111b`.

For example:

SADDR0101 0110b
SADEN1111 1100b
Given0101 01XXb

The following is an example of how to use given addresses to address different slaves:

Slave A:SADDR1111 0001b
SADEN1111 1010b
Given1111 0X0Xb

Slave B:SADDR1111 0011b
SADEN1111 1001b
Given1111 0XX1b

Slave C:SADDR1111 0010b
SADEN1111 1101b
Given1111 00X1b

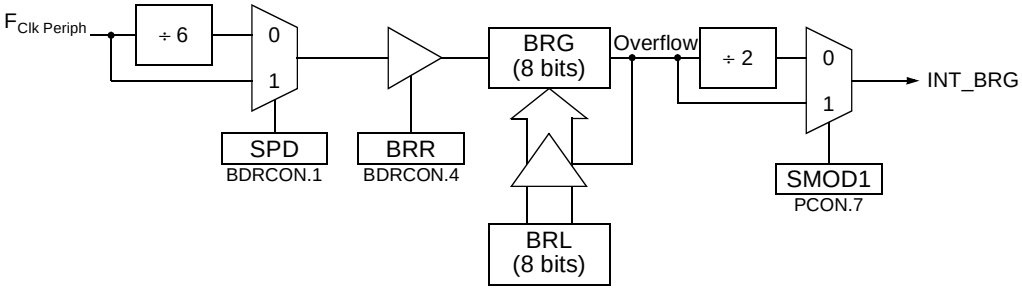
Table 32. Baud Rate Selection Table UART

TCLK (T2CON)	RCLK (T2CON)	TBCK (BDRCON)	RBCK (BDRCON)	Clock Source UART Tx	Clock Source UART Rx
0	0	0	0	Timer 1	Timer 1
1	0	0	0	Timer 2	Timer 1
0	1	0	0	Timer 1	Timer 2
1	1	0	0	Timer 2	Timer 2
X	0	1	0	INT_BRG	Timer 1
X	1	1	0	INT_BRG	Timer 2
0	X	0	1	Timer 1	INT_BRG
1	X	0	1	Timer 2	INT_BRG
X	X	1	1	INT_BRG	INT_BRG

Internal Baud Rate Generator (BRG)

When the internal Baud Rate Generator is used, the Baud Rates are determined by the BRG overflow depending on the BRL reload value, the value of SPD bit (Speed Mode) in BDRCON register and the value of the SMOD1 bit in PCON register.

Figure 21. Internal Baud Rate



- The baud rate for UART is token by formula:

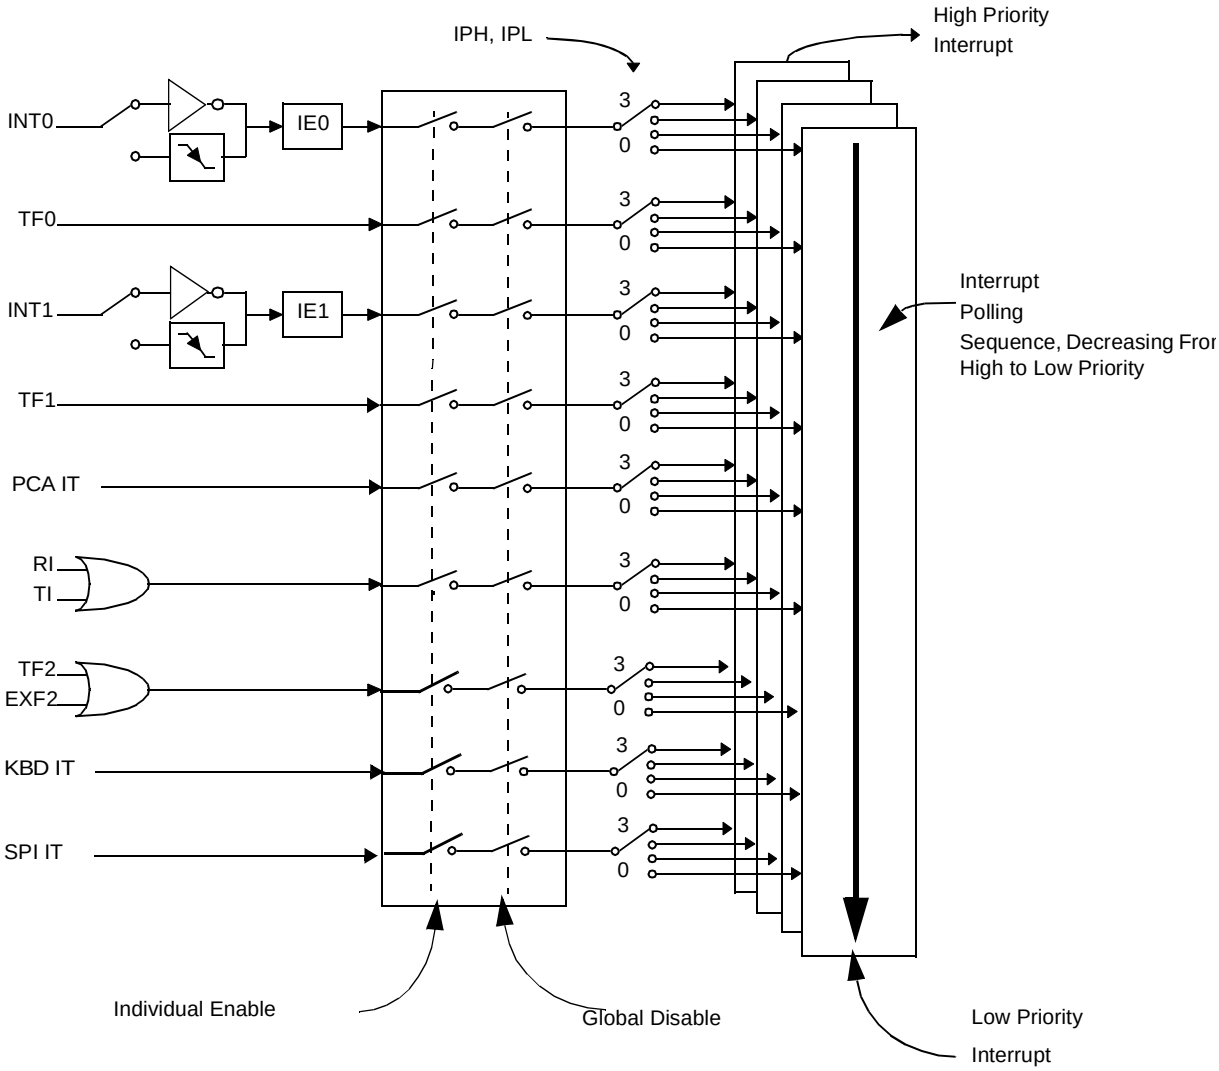
$$Baud\_Rate = \frac{2^{SMOD1} \cdot F_{PER}}{6^{(1-SPD)} \cdot 32 \cdot (256 - BRL)}$$

$$BRL = 256 - \frac{2^{SMOD1} \cdot F_{PER}}{6^{(1-SPD)} \cdot 32 \cdot Baud\_Rate}$$

Interrupt System

The AT89C51RB2/RC2 has a total of 9 interrupt vectors: two external interrupts ($\overline{INT0}$ and $\overline{INT1}$), three timer interrupts (timers 0, 1 and 2), the serial port interrupt, SPI interrupt, Keyboard interrupt and the PCA global interrupt. These interrupts are shown in Figure 22.

Figure 22. Interrupt Control System



Each of the interrupt sources can be individually enabled or disabled by setting or clearing a bit in the Interrupt Enable register (Table 45 and Table 47). This register also contains a global disable bit, which must be cleared to disable all interrupts at once.

Each interrupt source can also be individually programmed to one out of four priority levels by setting or clearing a bit in the Interrupt Priority register (Table 48) and in the Interrupt Priority High register (Table 46 and Table 47) shows the bit values and priority levels associated with each combination.

Interrupt Sources and Vector Addresses

Table 50. Interrupt Sources and Vector Addresses

Number	Polling Priority	Interrupt Source	Interrupt Request	Vector Address
0	0	Reset		0000h
1	1	INT0	IE0	0003h
2	2	Timer 0	TF0	000Bh
3	3	INT1	IE1	0013h
4	4	Timer 1	IF1	001Bh
5	6	UART	RI+TI	0023h
6	7	Timer 2	TF2+EXF2	002Bh
7	5	PCA	CF + CCFn (n = 0-4)	0033h
8	8	Keyboard	KBDIT	003Bh
9	9	SPI	SPIIT	004Bh

ONCE™ Mode (ON Chip Emulation)

The ONCE mode facilitates testing and debugging of systems using AT89C51RB2/RC2 without removing the circuit from the board. The ONCE mode is invoked by driving certain pins of the AT89C51RB2/RC2; the following sequence must be exercised:

- Pull ALE low while the device is in reset (RST high) and $\overline{\text{PSEN}}$ is high.
- Hold ALE low as RST is deactivated.

While the AT89C51RB2/RC2 is in ONCE mode, an emulator or test CPU can be used to drive the circuit. Table 61 shows the status of the port pins during ONCE mode.

Normal operation is restored when normal reset is applied.

Table 61. External Pin Status during ONCE Mode

ALE	PSEN	Port 0	Port 1	Port 2	Port 3	XTAL1/2
Weak pull-up	Weak pull-up	Float	Weak pull-up	Weak pull-up	Weak pull-up	Active

Table 1. Minimum Reset Capacitor Value for a 50 kΩ Pull-down Resistor(1)

Oscillator Start-Up Time	VDD Rise Time		
	1 ms	10 ms	100 ms
5 ms	820 nF	1.2 µF	12 µF
20 ms	2.7 µF	3.9 µF	12 µF

Note: These values assume V_{DD} starts from 0V to the nominal value. If the time between 2 on/off sequences is too fast, the power-supply de-coupling capacitors may not be fully discharged, leading to a bad reset sequence.

Warm Reset

To achieve a valid reset, the reset signal must be maintained for at least 2 machine cycles (24 oscillator clock periods) while the oscillator is running. The number of clock periods is mode independent (X2 or X1).

Watchdog Reset

As detailed in Section “Hardware Watchdog Timer”, page 77, the WDT generates a 96-clock period pulse on the RST pin. In order to properly propagate this pulse to the rest of the application in case of external capacitor or power-supply supervisor circuit, a 1 kΩ resistor must be added as shown Figure 33.

Figure 33. Reset Circuitry for WDT Reset-out Usage

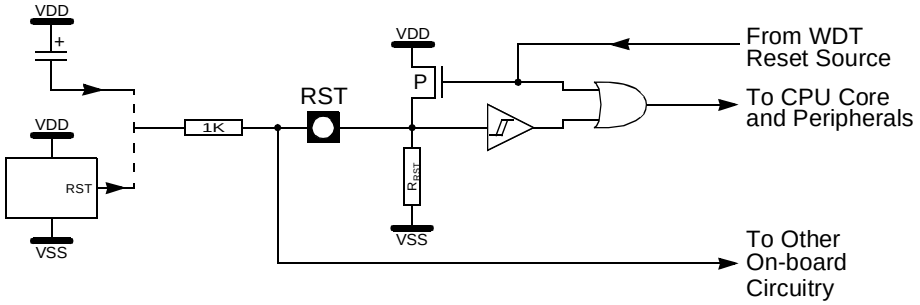


Figure 37. Bootloader Functional Description

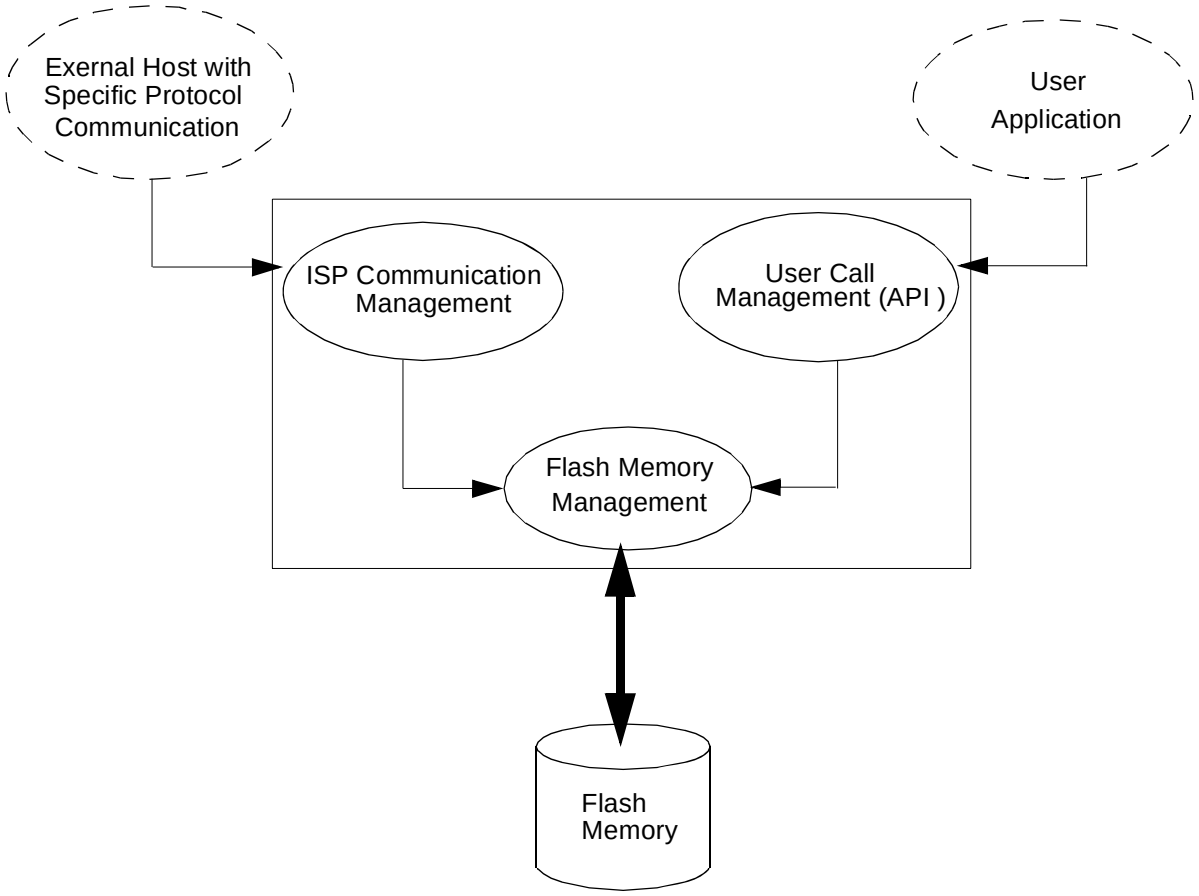

On the above diagram, the on-chip bootloader processes are:

- ISP Communication Management

The purpose of this process is to manage the communication and its protocol between the on-chip bootloader and a external device. The on-chip ROM implement a serial protocol (see section Bootloader Protocol). This process translate serial communication frame (UART) into Flash memory acess (read, write, erase ...).

- User Call Management

Several Application Program Interface (API) calls are available for use by an application program to permit selective erasing and programming of Flash pages. All calls are made through a common interface (API calls), included in the ROM bootloader. The programming functions are selected by setting up the microcontroller's registers before making a call to a common entry point (0xFFF0). Results are returned in the registers. The purpose on this process is to translate the registers values into internal Flash Memory Management.

- Flash Memory Management

This process manages low level access to Flash memory (performs read and write access).

Functional Description

Software Security Bits (SSB)

The SSB protects any Flash access from ISP command.
The command "Program Software Security bit" can only write a higher priority level.

There are three levels of security:

- level 0: ***NO_SECURITY*** (FFh)

This is the default level.
From level 0, one can write level 1 or level 2.

- level 1: ***WRITE_SECURITY*** (FEh)

For this level it is impossible to write in the Flash memory, BSB and SBV.
The Bootloader returns 'P' on write access.
From level 1, one can write only level 2.

- level 2: ***RD_WR_SECURITY*** (FCh

The level 2 forbids all read and write accesses to/from the Flash/EEPROM memory.
The Bootloader returns 'L' on read or write access.
Only a full chip erase in parallel mode (using a programmer) or ISP command can reset the software security bits.
From level 2, one cannot read and write anything.

Table 71. Software Security Byte Behavior

	Level 0	Level 1	Level 2
Flash/EEPROM	Any access allowed	Read only access allowed	Any access not allowed
Fuse Bit	Any access allowed	Read only access allowed	Any access not allowed
BSB & SBV	Any access allowed	Read only access allowed	Any access not allowed
SSB	Any access allowed	Write level 2 allowed	Read only access allowed
Manufacturer Info	Read only access allowed	Read only access allowed	Read only access allowed
Bootloader Info	Read only access allowed	Read only access allowed	Read only access allowed
Erase Block	Allowed	Not allowed	Not allowed
Full-chip Erase	Allowed	Allowed	Allowed
Blank Check	Allowed	Allowed	Allowed

Autobaud Performances

The ISP feature allows a wide range of baud rates in the user application. It is also adaptable to a wide range of oscillator frequencies. This is accomplished by measuring the bit-time of a single bit in a received character. This information is then used to program the baud rate in terms of timer counts based on the oscillator frequency. The ISP feature requires that an initial character (an uppercase U) be sent to the AT89C51RB2/RC2 to establish the baud rate. Table 72 shows the autobaud capability.

Table 72. Autobaud Performances

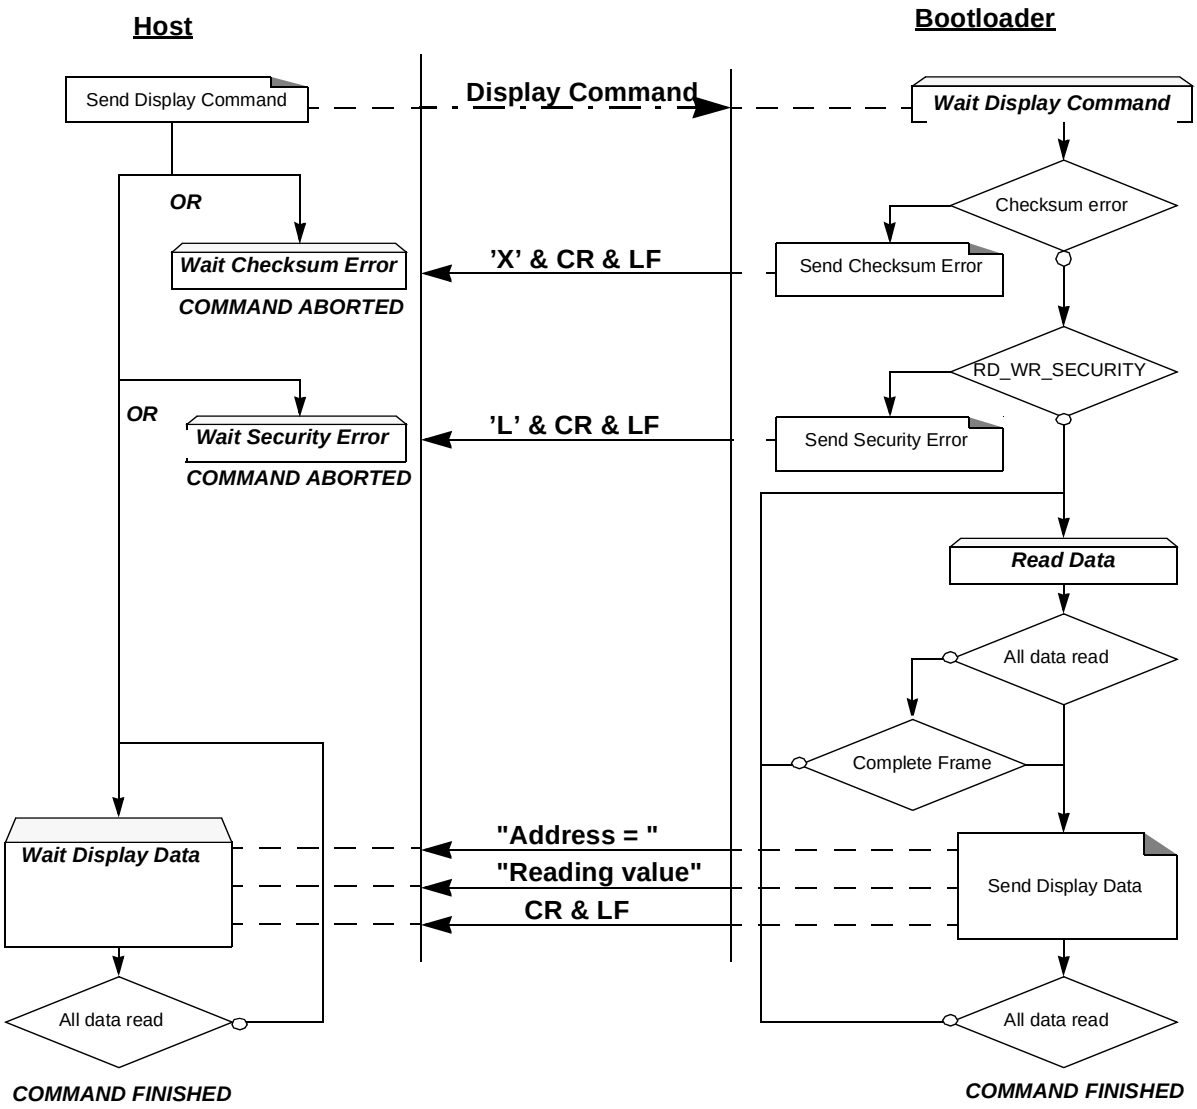
Command Data Stream Protocol

All commands are sent using the same flow. Each frame sent by the host is echoed by the bootloader.

Display Data

Description

Figure 44. Display Flow



Note: The maximum size of block is 400h. To read more than 400h Bytes, the Host must send a new command.

If I_{OL} exceeds the test condition, V_{OL} may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.

7. For other values, please contact your sales office.
8. Icc Flash Write operation current while an on-chip flash page write is on going.
