

Welcome to E-XFL.COM

#### What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

#### Applications of "<u>Embedded -</u> <u>Microcontrollers</u>"

#### Details

Product Status	Obsolete
Core Processor	S08
Core Size	8-Bit
Speed	40MHz
Connectivity	l²C, LINbus, SCI, SPI
Peripherals	LVD, POR, PWM, WDT
Number of I/O	25
Program Memory Size	16KB (16K x 8)
Program Memory Type	FLASH
EEPROM Size	512 x 8
RAM Size	1K x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 5.5V
Data Converters	A/D 10x12b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 125°C (TA)
Mounting Type	Surface Mount
Package / Case	48-LQFP
Supplier Device Package	48-LQFP (7x7)
Purchase URL	https://www.e-xfl.com/product-detail/nxp-semiconductors/s9s08dn16f1mlf

Email: info@E-XFL.COM

Address: Room A, 16/F, Full Win Commercial Centre, 573 Nathan Road, Mongkok, Hong Kong

**Chapter 2 Pins and Connections** 

# 2.2 Recommended System Connections

Figure 2-4 shows pin connections that are common to MC9S08DN60 Series application systems.

#### **Chapter 3 Modes of Operation**

Background commands are of two types:

- Non-intrusive commands, defined as commands that can be issued while the user program is running. Non-intrusive commands can be issued through the BKGD/MS pin while the MCU is in run mode; non-intrusive commands can also be executed when the MCU is in the active background mode. Non-intrusive commands include:
  - Memory access commands
  - Memory-access-with-status commands
  - BDC register access commands
  - The BACKGROUND command
- Active background commands, which can only be executed while the MCU is in active background mode. Active background commands include commands to:
  - Read or write CPU registers
  - Trace one user program instruction at a time
  - Leave active background mode to return to the user application program (GO)

The active background mode is used to program a bootloader or user application program into the Flash program memory before the MCU is operated in run mode for the first time. When the MC9S08DN60 Series is shipped from the Freescale Semiconductor factory, the Flash program memory is erased by default unless specifically noted so there is no program that could be executed in run mode until the Flash memory is initially programmed. The active background mode can also be used to erase and reprogram the Flash memory after it has been previously programmed.

For additional information about the active background mode, refer to the Development Support chapter.

# 3.5 Wait Mode

Wait mode is entered by executing a WAIT instruction. Upon execution of the WAIT instruction, the CPU enters a low-power state in which it is not clocked. The I bit in CCR is cleared when the CPU enters the wait mode, enabling interrupts. When an interrupt request occurs, the CPU exits the wait mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

While the MCU is in wait mode, there are some restrictions on which background debug commands can be used. Only the BACKGROUND command and memory-access-with-status commands are available when the MCU is in wait mode. The memory-access-with-status commands do not allow memory access, but they report an error indicating that the MCU is in either stop or wait mode. The BACKGROUND command can be used to wake the MCU from wait mode and enter active background mode.

## 4.4 RAM

The MC9S08DN60 Series includes static RAM. The locations in RAM below 0x0100 can be accessed using the more efficient direct addressing mode, and any single bit in this area can be accessed with the bit manipulation instructions (BCLR, BSET, BRCLR, and BRSET). Locating the most frequently accessed program variables in this area of RAM is preferred.

The RAM retains data while the MCU is in low-power wait, stop2, or stop3 mode. At power-on the contents of RAM are uninitialized. RAM data is unaffected by any reset if the supply voltage does not drop below the minimum value for RAM retention ( $V_{RAM}$ ).

For compatibility with M68HC05 MCUs, the HCS08 resets the stack pointer to 0x00FF. In the MC9S08DN60 Series, it is usually best to reinitialize the stack pointer to the top of the RAM so the direct page RAM can be used for frequently accessed RAM variables and bit-addressable program variables. Include the following 2-instruction sequence in your reset initialization routine (where RamLast is equated to the highest address of the RAM in the Freescale Semiconductor equate file).

LDHX #RamLast+1 ;point one past RAM TXS ;SP<-(H:X-1)

When security is enabled, the RAM is considered a secure memory resource and is not accessible through BDM or code executing from non-secure memory. See Section 4.5.9, "Security", for a detailed description of the security feature.

# 4.5 Flash and EEPROM

MC9S08DN60 Series devices include Flash and EEPROM memory intended primarily for program and data storage. In-circuit programming allows the operating program and data to be loaded into Flash and EEPROM, respectively, after final assembly of the application product. It is possible to program the arrays through the single-wire background debug interface. Because no special voltages are needed for erase and programming operations, in-application programming is also possible through other software-controlled communication paths. For a more detailed discussion of in-circuit and in-application programming, refer to the *HCS08 Family Reference Manual, Volume I*, Freescale Semiconductor document order number HCS08RMv1.

## 4.5.1 Features

Features of the Flash and EEPROM memory include:

- Array size (see Table 1-1 for exact array sizes)
- Flash sector size: 768 bytes
- EEPROM sector size: selectable 4-byte or 8-byte sector mapping operation
- Single power supply program and erase
- Command interface for fast program and erase operation
- Up to 100,000 program/erase cycles at typical voltage and temperature
- Flexible block protection and vector redirection
- Security feature for Flash, EEPROM, and RAM

## 6.5.1.7 Port A Interrupt Pin Select Register (PTAPS)

Figure 6-9. Port A Interrupt Pin Select Register (PTAPS)

### Table 6-7. PTAPS Register Field Descriptions

Field	Description

## 6.5.1.8 Port A Interrupt Edge Select Register (PTAES)

_	7	6	5	4	3	2	1	0
R W	PTAES7	PTAES6	PTAES5	PTAES4	PTAES3	PTAES2	PTAES1	PTAES0
Reset:	0	0	0	0	0	0	0	0

#### Figure 6-10. Port A Edge Select Register (PTAES)

#### Table 6-8. PTAES Register Field Descriptions

Field	Description
7:0 PTAES[7:0]	<ul> <li>Port A Edge Selects — Each of the PTAESn bits serves a dual purpose by selecting the polarity of the active interrupt edge as well as selecting a pull-up or pull-down device if enabled.</li> <li>0 A pull-up device is connected to the associated pin and detects falling edge/low level for interrupt generation.</li> <li>1 A pull-down device is connected to the associated pin and detects rising edge/high level for interrupt generation.</li> </ul>

## 6.5.4 Port D Registers

Port D is controlled by the registers listed below.

## 6.5.4.1 Port D Data Register (PTDD)

### Figure 6-24. Port D Data Register (PTDD)

#### Table 6-22. PTDD Register Field Descriptions

Field	Description
7:0 PTDD[7:0]	<b>Port D Data Register Bits</b> — For port D pins that are inputs, reads return the logic level on the pin. For port D pins that are configured as outputs, reads return the last value written to this register. Writes are latched into all bits of this register. For port D pins that are configured as outputs, the logic level is driven out the corresponding MCU pin. Reset forces PTDD to all 0s, but these 0s are not driven out the corresponding pins because reset also configures all port pins as high-impedance inputs with pull-ups/pull-downs disabled.

## 6.5.4.2 Port D Data Direction Register (PTDDD)

Field	Description
7:0 PTDDD[7:0]	<b>Data Direction for Port D Bits</b> — These read/write bits control the direction of port D pins and what is read for PTDD reads.
	<ol> <li>Input (output driver disabled) and reads return the pin value.</li> <li>Output driver enabled for port D bit n and PTDD reads return the contents of PTDDn.</li> </ol>

Chapter 7 Central Processor Unit (S08CPUV3)

# 7.2 Programmer's Model and CPU Registers

Figure 7-1 shows the five CPU registers. CPU registers are not part of the memory map.

Figure 7-1. CPU Registers

## 7.2.1 Accumulator (A)

The A accumulator is a general-purpose 8-bit register. One operand input to the arithmetic logic unit (ALU) is connected to the accumulator and the ALU results are often stored into the A accumulator after arithmetic and logical operations. The accumulator can be loaded from memory using various addressing modes to specify the address where the loaded data comes from, or the contents of A can be stored to memory using various addressing modes to specify the addressing modes to specify the addressing modes to specify the address where data from A will be stored.

Reset has no effect on the contents of the A accumulator.

## 7.2.2 Index Register (H:X)

This 16-bit register is actually two separate 8-bit registers (H and X), which often work together as a 16-bit address pointer where H holds the upper byte of an address and X holds the lower byte of the address. All indexed addressing mode instructions use the full 16-bit value in H:X as an index reference pointer; however, for compatibility with the earlier M68HC05 Family, some instructions operate only on the low-order 8-bit half (X).

Many instructions treat X as a second general-purpose 8-bit register that can be used to hold 8-bit data values. X can be cleared, incremented, decremented, complemented, negated, shifted, or rotated. Transfer instructions allow data to be transferred from A or transferred to A where arithmetic and logical operations can then be performed.

For compatibility with the earlier M68HC05 Family, H is forced to 0x00 during reset. Reset has no effect on the contents of X.

# 8.4 Functional Description

## 8.4.1 Operational Modes

Figure 8-8. Clock Switching Modes

Chapter 8 Multi-Purpose Clock Generator (S08MCGV1)

# 8.5.3 Calibrating the Internal Reference Clock (IRC)

The IRC is calibrated by writing to the MCGTRM register first, then using the FTRIM bit to "fine tune" the frequency. We will refer to this total 9-bit value as the trim value, ranging from 0x000 to 0x1FF, where the FTRIM bit is the LSB.

The trim value after a POR is always 0x100 (MCGTRM = 0x80 and FTRIM = 0). Writing a larger value will decrease the frequency and smaller values will increase the frequency. The trim value is linear with the period, except that slight variations in wafer fab processing produce slight non-linearities between trim value and period. These non-linearities are why an iterative trimming approach to search for the best trim value is recommended. In Example #5: Internal Reference Clock Trim this approach will be demonstrated.

After a trim value has been found for a device, this value can be stored in FLASH memory to save the value. If power is removed from the device, the IRC can easily be re-trimmed by copying the saved value from FLASH to the MCG registers. Freescale identifies recommended FLASH locations for storing the trim value for each MCU. Consult the memory map in the data sheet for these locations. On devices that are factory trimmed, the factory trim value will be stored in these locations.

## 8.5.3.1 Example #5: Internal Reference Clock Trim

For applications that require a tight frequency tolerance, a trimming procedure is provided that will allow a very accurate internal clock source. This section outlines one example of trimming the internal oscillator. Many other possible trimming procedures are valid and can be used.

In the example below, the MCG trim will be calibrated for the 9-bit MCGTRM and FTRIM collective value. This value will be referred to as TRMVAL.

# **10.5** Initialization Information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module. You can configure the module for 8-, 10-, or 12-bit resolution, single or continuous conversion, and a polled or interrupt approach, among many other options. Refer to Table 10-7, Table 10-8, and Table 10-9 for information used in this example.

### NOTE

Hexadecimal values designated by a preceding 0x, binary values designated by a preceding %, and decimal values have no preceding character.

## 10.5.1 ADC Module Initialization Example

### **10.5.1.1** Initialization Sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is as follows:

- 1. Update the configuration register (ADCCFG) to select the input clock source and the divide ratio used to generate the internal clock, ADCK. This register is also used for selecting sample time and low-power configuration.
- 2. Update status and control register 2 (ADCSC2) to select the conversion trigger (hardware or software) and compare function options, if enabled.
- 3. Update status and control register 1 (ADCSC1) to select whether conversions will be continuous or completed only once, and to enable or disable conversion complete interrupts. The input channel on which conversions will be performed is also selected here.

## 10.5.1.2 Pseudo-Code Example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low power with a long sample time on input channel 1, where the internal ADCK clock is derived from the bus clock divided by 1.

### ADCCFG = 0x98 (%10011000)

Bit 7	ADLPC	1	Configures for low power (lowers maximum clock speed)
Bit 6:5	ADIV	00	Sets the ADCK to the input clock $\div$ 1
Bit 4	ADLSMP	1	Configures for long sample time
Bit 3:2	MODE	10	Sets mode at 10-bit conversions
Bit 1:0	ADICLK	00	Selects bus clock as input clock source

#### ADCSC2 = 0x00 (%00000000)

Bit	7	ADACT	0
Bit	6	ADTRG	0
Bit	5	ACFE	0
Bit	4	ACFGT	0
Bit	3:2		00
Bit	1:0		00

Flag indicates if a conversion is in progress Software trigger selected Compare function disabled Not used in this example Reserved, always reads zero Reserved for Freescale's internal use; always write zero

![](_page_13_Picture_0.jpeg)

# **10.6** Application Information

This section contains information for using the ADC module in applications. The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an A/D converter.

## 10.6.1 External Pins and Routing

The following sections discuss the external pins associated with the ADC module and how they should be used for best results.

## 10.6.1.1 Analog Supply Pins

The ADC module has analog power and ground supplies ( $V_{DDAD}$  and  $V_{SSAD}$ ) available as separate pins on some devices.  $V_{SSAD}$  is shared on the same pin as the MCU digital  $V_{SS}$  on some devices. On other devices,  $V_{SSAD}$  and  $V_{DDAD}$  are shared with the MCU digital supply pins. In these cases, there are separate pads for the analog supplies bonded to the same pin as the corresponding digital supply so that some degree of isolation between the supplies is maintained.

When available on a separate pin, both  $V_{DDAD}$  and  $V_{SSAD}$  must be connected to the same voltage potential as their corresponding MCU digital supply ( $V_{DD}$  and  $V_{SS}$ ) and must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

If separate power supplies are used for analog and digital power, the ground connection between these supplies must be at the  $V_{SSAD}$  pin. This should be the only ground connection between these supplies if possible. The  $V_{SSAD}$  pin makes a good single point ground location.

## 10.6.1.2 Analog Reference Pins

In addition to the analog supplies, the ADC module has connections for two reference voltage inputs. The high reference is  $V_{REFH}$ , which may be shared on the same pin as  $V_{DDAD}$  on some devices. The low reference is  $V_{REFL}$ , which may be shared on the same pin as  $V_{SSAD}$  on some devices.

When available on a separate pin,  $V_{REFH}$  may be connected to the same potential as  $V_{DDAD}$ , or may be driven by an external source between the minimum  $V_{DDAD}$  spec and the  $V_{DDAD}$  potential ( $V_{REFH}$  must never exceed  $V_{DDAD}$ ). When available on a separate pin,  $V_{REFL}$  must be connected to the same voltage potential as  $V_{SSAD}$ .  $V_{REFH}$  and  $V_{REFL}$  must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

AC current in the form of current spikes required to supply charge to the capacitor array at each successive approximation step is drawn through the  $V_{REFH}$  and  $V_{REFL}$  loop. The best external component to meet this current demand is a 0.1  $\mu$ F capacitor with good high frequency characteristics. This capacitor is connected between  $V_{REFH}$  and  $V_{REFL}$  and must be placed as near as possible to the package pins. Resistance in the path is not recommended because the current causes a voltage drop that could result in conversion errors. Inductance in this path must be minimum (parasitic only).

![](_page_14_Picture_1.jpeg)

## 11.1.1 Features

The IIC includes these distinctive features:

- Compatible with IIC bus standard
- Multi-master operation
- Software programmable for one of 64 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- General call recognition
- 10-bit address extension

## 11.1.2 Modes of Operation

A brief description of the IIC in the various MCU modes is given here.

- **Run mode** This is the basic mode of operation. To conserve power in this mode, disable the module.
- Wait mode The module continues to operate while the MCU is in wait mode and can provide a wake-up interrupt.
- **Stop mode** The IIC is inactive in stop3 mode for reduced power consumption. The stop instruction does not affect IIC register states. Stop2 resets the register contents.

#### Table 12-3. SPIC2 Register Field Descriptions

Field	Description				
4 MODFEN	<ul> <li>Master Mode-Fault Function Enable — When the SPI is configured for slave mode, this bit has no meaning or effect. (The SS pin is the slave select input.) In master mode, this bit determines how the SS pin is used (refer to Table 12-2 for more details).</li> <li>Mode fault function disabled, master SS pin reverts to general-purpose I/O not controlled by SPI</li> <li>Mode fault function enabled, master SS pin acts as the mode fault input or the slave select output</li> </ul>				
3 BIDIROE	<b>Bidirectional Mode Output Enable</b> — When bidirectional mode is enabled by SPI pin control 0 (SPC0) = 1, BIDIROE determines whether the SPI data output driver is enabled to the single bidirectional SPI I/O pin. Depending on whether the SPI is configured as a master or a slave, it uses either the MOSI (MOMI) or MISO (SISO) pin, respectively, as the single SPI data I/O pin. When SPC0 = 0, BIDIROE has no meaning or effect. 0 Output driver disabled so SPI data I/O pin acts as an input 1 SPI I/O pin enabled as an output				
1 SPISWAI	SPI Stop in Wait Mode         0       SPI clocks continue to operate in wait mode         1       SPI clocks stop when the MCU enters wait mode				
0 SPC0	<ul> <li>SPI Pin Control 0 — The SPC0 bit chooses single-wire bidirectional mode. If MSTR = 0 (slave mode), the SPI uses the MISO (SISO) pin for bidirectional SPI data transfers. If MSTR = 1 (master mode), the SPI uses the MOSI (MOMI) pin for bidirectional SPI data transfers. When SPC0 = 1, BIDIROE is used to enable or disable the output driver for the single bidirectional SPI I/O pin.</li> <li>O SPI uses separate pins for data input and data output</li> <li>1 SPI configured for single-wire bidirectional operation</li> </ul>				

## 12.4.3 SPI Baud Rate Register (SPIBR)

This register is used to set the prescaler and bit rate divisor for an SPI master. This register may be read or written at any time.

![](_page_16_Figure_6.jpeg)

= Unimplemented or Reserved

### Figure 12-7. SPI Baud Rate Register (SPIBR)

#### Table 12-4. SPIBR Register Field Descriptions

Field	Description
6:4 SPPR[2:0]	<b>SPI Baud Rate Prescale Divisor</b> — This 3-bit field selects one of eight divisors for the SPI baud rate prescaler as shown in Table 12-5. The input to this prescaler is the bus rate clock (BUSCLK). The output of this prescaler drives the input of the SPI baud rate divider (see Figure 12-4).
2:0 SPR[2:0]	<b>SPI Baud Rate Divisor</b> — This 3-bit field selects one of eight divisors for the SPI baud rate divider as shown in Table 12-6. The input to this divider comes from the SPI baud rate prescaler (see Figure 12-4). The output of this divider is the SPI bit rate clock for master mode.

**Chapter 16 Development Support** 

## 16.1.2 Features

Features of the BDC module include:

- Single pin for mode selection and background communications
- BDC registers are not located in the memory map
- SYNC command to determine target communications rate
- Non-intrusive commands for memory access
- Active background mode commands for CPU register access
- GO and TRACE1 commands
- BACKGROUND command can wake CPU from stop or wait modes
- One hardware address breakpoint built into BDC
- Oscillator runs in stop mode, if BDC enabled
- COP watchdog disabled while in active background mode

Features of the ICE system include:

- Two trigger comparators: Two address + read/write (R/W) or one full address + data + R/W
- Flexible 8-word by 16-bit FIFO (first-in, first-out) buffer for capture information:
  - Change-of-flow addresses or
  - Event-only data
- Two types of breakpoints:
  - Tag breakpoints for instruction opcodes
  - Force breakpoints for any address access
- Nine trigger modes:
  - Basic: A-only, A OR B
  - Sequence: A then B
  - Full: A AND B data, A AND NOT B data
  - Event (store data): Event-only B, A then event-only B
  - Range: Inside range (A  $\leq$  address  $\leq$  B), outside range (address < A or address > B)

# 16.2 Background Debug Controller (BDC)

All MCUs in the HCS08 Family contain a single-wire background debug interface that supports in-circuit programming of on-chip nonvolatile memory and sophisticated non-intrusive debug capabilities. Unlike debug interfaces on earlier 8-bit MCUs, this system does not interfere with normal application resources. It does not use any user memory or locations in the memory map and does not share any on-chip peripherals.

BDC commands are divided into two groups:

• Active background mode commands require that the target MCU is in active background mode (the user program is not running). Active background mode commands allow the CPU registers to be read or written, and allow the user to trace one user instruction at a time, or GO to the user program from active background mode.

![](_page_18_Picture_0.jpeg)

**Chapter 16 Development Support** 

# 16.2.3 BDC Commands

BDC commands are sent serially from a host computer to the BKGD pin of the target HCS08 MCU. All commands and data are sent MSB-first using a custom BDC communications protocol. Active background mode commands require that the target MCU is currently in the active background mode while non-intrusive commands may be issued at any time whether the target MCU is in active background mode or running a user application program.

Table 16-1 shows all HCS08 BDC commands, a shorthand description of their coding structure, and the meaning of each command.

## **Coding Structure Nomenclature**

This nomenclature is used in Table 16-1 to describe the coding structure of the BDC commands.

Commands begin with an 8-bit hexadecimal command code in the host-to-target direction (most significant bit first)

- / = separates parts of the command
- d = delay 16 target BDC clock cycles
- AAAA = a 16-bit address in the host-to-target direction
  - RD = 8 bits of read data in the target-to-host direction
  - WD = 8 bits of write data in the host-to-target direction
- RD16 = 16 bits of read data in the target-to-host direction
- WD16 = 16 bits of write data in the host-to-target direction
  - SS = the contents of BDCSCR in the target-to-host direction (STATUS)
  - CC = 8 bits of write data for BDCSCR in the host-to-target direction (CONTROL)
- RBKP = 16 bits of read data in the target-to-host direction (from BDCBKPT breakpoint register)
- WBKP = 16 bits of write data in the host-to-target direction (for BDCBKPT breakpoint register)

# A.12.3 SPI

Table A-15 and Figure A-7 through Figure A-10 describe the timing requirements for the SPI system.

Num <sup>1</sup>	С	Rating <sup>2</sup>	Symbol	Min	Max	Unit
1	D	Cycle time Master Slave	t <sub>SCK</sub> t <sub>SCK</sub>	2 4	2048	t <sub>cyc</sub> t <sub>cyc</sub>
2	D	Enable lead time Master Slave	t <sub>Lead</sub> t <sub>Lead</sub>	 1/2	1/2	t <sub>SCK</sub> t <sub>SCK</sub>
3	D	Enable lag time Master Slave	t <sub>Lag</sub> t <sub>Lag</sub>	 1/2	1/2	t <sub>SCK</sub> t <sub>SCK</sub>
4	D	Clock (SPSCK) high time Master and Slave	t <sub>SCKH</sub>	(1/2 t <sub>SCK</sub> )– 25	_	ns
5	D	Clock (SPSCK) low time Master and Slave	t <sub>SCKL</sub>	(1/2 t <sub>SCK</sub> ) – 25	_	ns
6	D	Data setup time (inputs) Master Slave	t <sub>SI(M)</sub> t <sub>SI(S)</sub>	30 30		ns ns
7	D	Data hold time (inputs) Master Slave	t <sub>HI(M)</sub> t <sub>HI(S)</sub>	30 30		ns ns
8	D	Access time, slave <sup>3</sup>	t <sub>A</sub>	0	40	ns
9	D	Disable time, slave <sup>4</sup>	t <sub>dis</sub>	_	40	ns
10	D	Data setup time (outputs) Master Slave	t <sub>SO</sub> t <sub>SO</sub>	25 25		ns ns
11	D	Data hold time (outputs) Master Slave	t <sub>HO</sub> t <sub>HO</sub>	-10 -10		ns ns
12	D	Operating frequency <sup>5</sup> Master Slave	f <sub>op</sub> f <sub>op</sub>	f <sub>Bus</sub> /2048 dc	5 f <sub>Bus</sub> /4	MHz

Table A-15. SPI Electrical Characteristic

<sup>1</sup> Refer to Figure A-7 through Figure A-10.

<sup>2</sup> All timing is shown with respect to 20% V<sub>DD</sub> and 70% V<sub>DD</sub>, unless noted; 100 pF load on all SPI pins. All timing assumes slew rate control disabled and high drive strength enabled for SPI output pins.

<sup>3</sup> Time to data active from high-impedance state.

<sup>4</sup> Hold time to high-impedance state.

<sup>5</sup> Maximum baud rate must be limited to 5 MHz due to pad input characteristics.
