

Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "<u>Embedded -</u> <u>Microcontrollers</u>"

Details

E·XFI

Details	
Product Status	Obsolete
Core Processor	PIC
Core Size	16-Bit
Speed	32MHz
Connectivity	I ² C, SPI, UART/USART, USB OTG
Peripherals	Brown-out Detect/Reset, LVD, POR, PWM, WDT
Number of I/O	51
Program Memory Size	192KB (65.5K x 24)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	16K x 8
Voltage - Supply (Vcc/Vdd)	2V ~ 3.6V
Data Converters	A/D 16x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	64-TQFP
Supplier Device Package	64-TQFP (10x10)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic24fj192gb106t-i-pt

Email: info@E-XFL.COM

Address: Room A, 16/F, Full Win Commercial Centre, 573 Nathan Road, Mongkok, Hong Kong

1.2 USB On-The-Go

With the PIC24FJ256GB110 family of devices, Microchip introduces USB On-The-Go functionality on a single chip to its product line. This new module provides on-chip functionality as a target device compatible with the USB 2.0 standard, as well as limited stand-alone functionality as a USB embedded host. By implementing USB Host Negotiation Protocol (HNP), the module can also dynamically switch between device and host operation, allowing for a much wider range of versatile USB-enabled applications on a microcontroller platform.

In addition to USB host functionality, PIC24FJ256GB110 family devices provide a true single-chip USB solution, including an on-chip transceiver and voltage regulator, and a voltage boost generator for sourcing bus power during host operations.

1.3 Other Special Features

- Peripheral Pin Select: The Peripheral Pin Select (PPS) feature allows most digital peripherals to be mapped over a fixed set of digital I/O pins. Users may independently map the input and/or output of any one of the many digital peripherals to any one of the I/O pins.
- **Communications:** The PIC24FJ256GB110 family incorporates a range of serial communication peripherals to handle a range of application requirements. There are three independent I²C modules that support both Master and Slave modes of operation. Devices also have, through the Peripheral Pin Select feature, four independent UARTs with built-in IrDA encoder/decoders and three SPI modules.
- Analog Features: All members of the PIC24FJ256GB110 family include a 10-bit A/D Converter module and a triple comparator module. The A/D module incorporates programmable acquisition time, allowing for a channel to be selected and a conversion to be initiated without waiting for a sampling period, as well as faster sampling speeds. The comparator module includes three analog comparators that are configurable for a wide range of operations.
- **CTMU Interface:** In addition to their other analog features, members of the PIC24FJ256GB110 family include the brand new CTMU interface module. This provides a convenient method for precision time measurement and pulse generation, and can serve as an interface for capacitive sensors.

- Parallel Master/Enhanced Parallel Slave Port: One of the general purpose I/O ports can be reconfigured for enhanced parallel data communications. In this mode, the port can be configured for both master and slave operations, and supports 8-bit and 16-bit data transfers with up to 16 external address lines in Master modes.
- Real-Time Clock/Calendar: This module implements a full-featured clock and calendar with alarm functions in hardware, freeing up timer resources and program memory space for use of the core application.

1.4 Details on Individual Family Members

Devices in the PIC24FJ256GB110 family are available in 64-pin, 80-pin and 100-pin packages. The general block diagram for all devices is shown in Figure 1-1.

The devices are differentiated from each other in four ways:

- Flash program memory (64 Kbytes for PIC24FJ64GB1 devices, 128 Kbytes for PIC24FJ128GB1 devices, 192 Kbytes for PIC24FJ192GB1 devices and 256 Kbytes for PIC24FJ256GB1 devices).
- Available I/O pins and ports (51 pins on 6 ports for 64-pin devices, 65 pins on 7 ports for 80-pin devices and 83 pins on 7 ports for 100-pin devices).
- 3. Available Interrupt-on-Change Notification (ICN) inputs (49 on 64-pin devices, 63 on 80-pin devices and 81 on 100-pin devices).
- 4. Available remappable pins (29 pins on 64-pin devices, 40 pins on 80-pin devices and 44 pins on 100-pin devices)

All other features for devices in this family are identical. These are summarized in Table 1-1.

A list of the pin features available on the PIC24FJ256GB110 family devices, sorted by function, is shown in Table 1-4. Note that this table shows the pin location of individual peripheral features and not how they are multiplexed on the same pin. This information is provided in the pinout diagrams in the beginning of the data sheet. Multiplexed features are sorted by the priority given to a feature, with the highest priority peripheral being listed first.

		Pin Number		I/O		
Function	64-Pin TQFP, QFN	80-Pin TQFP	100-Pin TQFP	I/O	Input Buffer	Description
D+	37	47	57	I/O	—	USB Differential Plus line (internal transceiver).

TABLE 6-3: RESET DELAY TIMES FOR VARIOUS DEVICE RESETS

Reset Type	Clock Source	SYSRST Delay	System Clock Delay	Notes
POR ⁽⁶⁾	EC	TPOR + TPWRT	_	1, 2
	FRC, FRCDIV	TPOR + TPWRT	TFRC	1, 2, 3, 6
	LPRC	TPOR + TPWRT	TLPRC	1, 2, 3
	ECPLL	TPOR + TPWRT	Тьоск	1, 2, 4
	FRCPLL	TPOR + TPWRT	TFRC + TLOCK	1, 2, 3, 4
	XT, HS, SOSC	TPOR+ TPWRT	Тоѕт	1, 2, 5
	XTPLL, HSPLL	TPOR + TPWRT	Tost + Tlock	1, 2, 4, 5
BOR	EC	TPWRT	_	2
	FRC, FRCDIV	TPWRT	TFRC	2, 3, 6
	LPRC	TPWRT	TLPRC	2, 3
	ECPLL	TPWRT	Тьоск	2, 4
	FRCPLL	TPWRT	TFRC + TLOCK	2, 3, 4
	XT, HS, SOSC	TPWRT	Tost	2, 5
	XTPLL, HSPLL	TPWRT	TFRC + TLOCK	2, 3, 4
All Others	Any Clock	_	_	—

Note 1: TPOR = Power-on Reset delay.

- 2: TPWRT = 64 ms nominal if regulator is disabled (ENVREG tied to Vss).
- 3: TFRC and TLPRC = RC Oscillator start-up times.
- **4:** TLOCK = PLL lock time.

5: TOST = Oscillator Start-up Timer (OST). A 10-bit counter waits 1024 oscillator periods before releasing oscillator clock to the system.

6: If Two-Speed Start-up is enabled, regardless of the Primary Oscillator selected, the device starts with FRC, and in such cases, FRC start-up time is valid.

Note: For detailed operating frequency and timing specifications, see Section 29.0 "Electrical Characteristics".

BDs have a fixed relationship to a particular endpoint, depending on the buffering configuration. Table 18-2 provides the mapping of BDs to endpoints. This relationship also means that gaps may occur in the BDT if endpoints are not enabled contiguously. This theoretically means that the BDs for disabled endpoints could be used as buffer space. In practice, users should avoid using such spaces in the BDT unless a method of validating BD addresses is implemented.

18.2.1 BUFFER OWNERSHIP

Because the buffers and their BDs are shared between the CPU and the USB module, a simple semaphore mechanism is used to distinguish which is allowed to update the BD and associated buffers in memory. This is done by using the UOWN bit as a semaphore to distinguish which is allowed to update the BD and associated buffers in memory. UOWN is the only bit that is shared between the two configurations of BDnSTAT.

When UOWN is clear, the BD entry is "owned" by the microcontroller core. When the UOWN bit is set, the BD entry and the buffer memory are "owned" by the USB peripheral. The core should not modify the BD or its corresponding data buffer during this time. Note that the microcontroller core can still read BDnSTAT while the SIE owns the buffer and vice versa.

The buffer descriptors have a different meaning based on the source of the register update. Register 18-1 and Register 18-2 show the differences in BDnSTAT depending on its current "ownership".

When UOWN is set, the user can no longer depend on the values that were written to the BDs. From this point, the USB module updates the BDs as necessary, overwriting the original BD values. The BDnSTAT register is updated by the SIE with the token PID and the transfer count is updated.

18.2.2 DMA INTERFACE

The USB OTG module uses a dedicated DMA to access both the BDT and the endpoint data buffers. Since part of the address space of the DMA is dedicated to the Buffer Descriptors, a portion of the memory connected to the DMA must comprise a contiguous address space properly mapped for the access by the module.

TABLE 18-2 :	ASSIGNMENT OF BUFFER DESCRIPTORS FOR THE DIFFERENT
	BUFFERING MODES

	BDs Assigned to Endpoint							
Endpoint	Mode 0 (No Ping-Pong)		Mode 1 (Ping-Pong on EP0 Out)		Mode 2 (Ping-Pong on all EPs)		Mode 3 (Ping-Pong on all other EPs, except EP0)	
	Out	In	Out	In	Out	In	Out	In

18.5.3 SEND A FULL-SPEED BULK DATA TRANSFER TO A TARGET DEVICE

- Follow the procedure described in Section 18.5.1 "Enable Host Mode and Discover a Connected Device" and Section 18.5.2 "Complete a Control Transaction to a Connected Device" to discover and configure a device.
- To enable transmit and receive transfers with handshaking enabled, write 1Dh to U1EP0. If the target device is a low-speed device, also set the LSPD bit (U1EP0<7>). If you want the hardware to automatically retry indefinitely if the target device asserts a NAK on the transfer, clear the Retry Disable bit, RETRYDIS (U1EP0<6>).
- 3. Set up the BD for the current (EVEN or ODD) Tx EP0 to transfer up to 64 bytes.
- 4. Set the USB device address of the target device in the address register (U1ADDR<6:0>).
- 5. Write an OUT token to the desired endpoint to U1TOK. This triggers the module's transmit state machines to begin transmitting the token and the data.
- 6. Wait for the Transfer Done Interrupt Flag, TRNIF. This indicates that the BD has been released back to the microprocessor, and the transfer has completed. If the retry disable bit is set, the handshake (ACK, NAK, STALL or ERROR (0Fh)) is returned in the BD PID field. If a STALL interrupt occurs, the pending packet must be dequeued and the error condition in the target device cleared. If a detach interrupt occurs (SE0 for more than 2.5 µs), then the target has detached (U1IR<0> is set).
- 7. Once the transfer done interrupt occurs (TRNIF is set), the BD can be examined and the next data packet queued by returning to step 2.
- **Note:** USB speed, transceiver and pull-ups should only be configured during the module setup phase. It is not recommended to change these settings while the module is enabled.

18.6 OTG Operation

18.6.1 SESSION REQUEST PROTOCOL (SRP)

An OTG A-device may decide to power down the VBUS supply when it is not using the USB link through the Session Request Protocol (SRP). Software may do this by clearing VBUSON (U10TGCON<3>). When the VBUS supply is powered down, the A-device is said to have ended a USB session.

An OTG A-device or Embedded Host may repower the VBUS supply at any time (initiate a new session). An OTG B-device may also request that the OTG A-device repower the VBUS supply (initiate a new session). This is accomplished via Session Request Protocol (SRP).

Prior to requesting a new session, the B-device must first check that the previous session has definitely ended. To do this, the B-device must check for two conditions:

1. VBUS supply is below the Session Valid voltage and

2. Both D+ and D- have been low for at least 2 ms.

The B-device will be notified of condition 1 by the SESENDIF (U1OTGIR<2>) interrupt. Software will have to manually check for condition 2.

Note:	When the A-device powers down the VBUS				
	supply, the B-device must disconnect its				
	pull-up resistor from power. If the device is				
	self-powered, it can do this by clearing				
	DPPULUP (U1OTGCON<7>) and				
	DMPULUP (U1OTGCON<6>).				

The B-device may aid in achieving condition 1 by discharging the VBUS supply through a resistor. Software may do this by setting VBUSDIS (U10TGCON<0>).

After these initial conditions are met, the B-device may begin requesting the new session. The B-device begins by pulsing the D+ data line. Software should do this by setting DPPULUP (U10TGCON<7>). The data line should be held high for 5 to 10 ms.

The B-device then proceeds by pulsing the VBUS supply. Software should do this by setting PUVBUS (U1CNFG2<4>). When an A-device detects SRP signaling (either via the ATTACHIF (U1IR<6>) interrupt or via the SESVDIF (U1OTGIR<3>) interrupt), the A-device must restore the VBUS supply by either setting VBUSON (U1OTGCON<3>), or by setting the I/O port controlling the external power source.

The B-device should not monitor the state of the VBUS supply while performing VBUS supply pulsing. When the B-device does detect that the VBUS supply has been restored (via the SESVDIF (U1OTGIR<3>) interrupt), the B-device must re-connect to the USB link by pulling up D+ or D- (via the DPPULUP or DMPULUP).

The A-device must complete the SRP by driving USB Reset signaling.
