Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details

Product Status	Obsolete
Number of LABs/CLBs	200
Number of Logic Elements/Cells	-
Total RAM Bits	-
Number of I/O	80
Number of Gates	1500
Voltage - Supply	4.5V ~ 5.5V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 85°C (TA)
Package / Case	100-BQFP
Supplier Device Package	100-PQFP (20x14)
Purchase URL	https://www.e-xfl.com/product-detail/microsemi/a1415a-pq100i

3.3 V Operating Conditions

Table 2-5 • Absolute Maximum Ratings¹, Free Air Temperature Range

Symbol	Parameter	Limits	Units
VCC	DC supply voltage	−0.5 to +7.0	V
VI	Input voltage	−0.5 to VCC + 0.5	V
VO	Output voltage	−0.5 to VCC + 0.5	V
IIO	I/O source sink current ²	±20	mA
T _{STG}	Storage temperature	−65 to +150	°C

Notes:

- Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. Exposure to absolute maximum rated conditions for extended periods may affect device reliability. Device should not be operated outside the recommended operating conditions.
- Device inputs are normally high impedance and draw extremely low current. However, when input voltage is greater than VCC + 0.5 V for less than GND −0.5 V, the internal protection diodes will forward bias and can draw excessive current.

Table 2-6 • Recommended Operating Conditions

Parameter	Commercial	Units
Temperature range*	0 to +70	°C
Power supply tolerance	3.0 to 3.6	V

Note: *Ambient temperature (T_A) is used for commercial.

Table 2-7 • Electrical Specifications

Parameter		Commercial		Units
		Min.	Max.	
VOH ¹	I _{OH} = −4 mA	2.15	–	V
	I _{OH} = −3.2 mA	2.4		V
VOL ¹	I _{OL} = 6 mA		0.4	V
VIL		−0.3	0.8	V
VIH		2.0	VCC + 0.3	V
Input transition time t _R , t _F ²	VI = VCC or GND	−10	+10	μA
C _{IO} I/O Capacitance ^{2,3}			10	pF
Standby current, ICC ⁴ (typical = 0.3 mA)			0.75	mA
Leakage current ⁵		−10	10	μA

- Only one output tested at a time. VCC = minimum.
- Not tested; for information only.
- Includes worst-case 84-pin PLCC package capacitance. VOUT = 0 V, f = 1 MHz.
- Typical standby current = 0.3 mA. All outputs unloaded. All inputs = VCC or GND.
- VO, VIN = VCC or GND

Power Dissipation

$$P = [ICC_{\text{standby}} + I_{\text{active}}] * VCC * IOL * VOL * N + IOH * (VCC - VOH) * M$$

EQ 3

where:

ICC standby is the current flowing when no inputs or outputs are changing

Iactive is the current flowing due to CMOS switching.

IOL and IOH are TTL sink/source current.

VOL and VOH are TTL level output voltages.

N is the number of outputs driving TTL loads to VOL.

M equals the number of outputs driving TTL loads to VOH.

An accurate determination of N and M is problematical because their values depend on the design and on the system I/O. The power can be divided into two components: static and active.

Static Power Component

Microsemi FPGAs have small static power components that result in lower power dissipation than PALs or PLDs. By integrating multiple PALs/PLDs into one FPGA, an even greater reduction in board-level power dissipation can be achieved.

The power due to standby current is typically a small component of the overall power. Standby power is calculated in Table 2-9 for commercial, worst case conditions.

Table 2-9 • Standby Power Calculation

ICC	VCC	Power
2 mA	5.25 V	10.5 mW

The static power dissipated by TTL loads depends on the number of outputs driving high or low and the DC load current. Again, this value is typically small. For instance, a 32-bit bus sinking 4 mA at 0.33 V will generate 42 mW with all outputs driving low, and 140 mW with all outputs driving high. The actual dissipation will average somewhere between as I/Os switch states with time.

Active Power Component

Power dissipation in CMOS devices is usually dominated by the active (dynamic) power dissipation. This component is frequency dependent, a function of the logic and the external I/O. Active power dissipation results from charging internal chip capacitances of the interconnect, unprogrammed antifuses, module inputs, and module outputs, plus external capacitance due to PC board traces and load device inputs.

An additional component of the active power dissipation is the totem-pole current in CMOS transistor pairs. The net effect can be associated with an equivalent capacitance that can be combined with frequency and voltage to represent active power dissipation.

Equivalent Capacitance

The power dissipated by a CMOS circuit can be expressed by EQ 4.

$$\text{Power } (\mu\text{W}) = C_{\text{EQ}} * VCC^2 * F$$

EQ 4

Where:

C_{EQ} is the equivalent capacitance expressed in pF.

VCC is the power supply in volts.

F is the switching frequency in MHz.

Equivalent capacitance is calculated by measuring ICC active at a specified frequency and voltage for each circuit component of interest. Measurements have been made over a range of frequencies at a fixed value of VCC. Equivalent capacitance is frequency independent so that the results may be used over a wide range of operating conditions. Equivalent capacitance values are shown in Figure 2-10.

Table 2-10 • CEQ Values for Microsemi FPGAs

Item	CEQ Value
Modules (C_{EQM})	6.7
Input Buffers (C_{EQI})	7.2
Output Buffers (C_{EQO})	10.4
Routed Array Clock Buffer Loads (C_{EQCR})	1.6
Dedicated Clock Buffer Loads (C_{EQCD})	0.7
I/O Clock Buffer Loads (C_{EQCI})	0.9

To calculate the active power dissipated from the complete design, the switching frequency of each part of the logic must be known. EQ 5 shows a piece-wise linear summation over all components.

$$\begin{aligned}
 \text{Power} = & VCC^2 * [(m * C_{EQM} * f_m)_{\text{modules}} + (n * C_{EQI} * f_n)_{\text{inputs}} \\
 & + (p * (C_{EQO} + C_L) * f_p)_{\text{outputs}} \\
 & + 0.5 * (q1 * C_{EQCR} * f_{q1})_{\text{routed_Clk1}} + (r1 * f_{q1})_{\text{routed_Clk1}} \\
 & + 0.5 * (q2 * C_{EQCR} * f_{q2})_{\text{routed_Clk2}} \\
 & + (r2 * f_{q2})_{\text{routed_Clk2}} + 0.5 * (s1 * C_{EQCD} * f_{s1})_{\text{dedicated_Clk}} \\
 & + (s2 * C_{EQCI} * f_{s2})_{\text{IO_Clk}}]
 \end{aligned}$$

EQ 5

Where:

m = Number of logic modules switching at f_m

n = Number of input buffers switching at f_n

p = Number of output buffers switching at f_p

q1 = Number of clock loads on the first routed array clock

q2 = Number of clock loads on the second routed array clock

r1 = Fixed capacitance due to first routed array clock

r2 = Fixed capacitance due to second routed array clock

s1 = Fixed number of clock loads on the dedicated array clock

s2 = Fixed number of clock loads on the dedicated I/O clock

C_{EQM} = Equivalent capacitance of logic modules in pF

C_{EQI} = Equivalent capacitance of input buffers in pF

C_{EQO} = Equivalent capacitance of output buffers in pF

C_{EQCR} = Equivalent capacitance of routed array clock in pF

C_{EQCD} = Equivalent capacitance of dedicated array clock in pF

C_{EQCI} = Equivalent capacitance of dedicated I/O clock in pF

C_L = Output lead capacitance in pF

f_m = Average logic module switching rate in MHz

f_n = Average input buffer switching rate in MHz

f_p = Average output buffer switching rate in MHz

f_{q1} = Average first routed array clock rate in MHz

f_{q2} = Average second routed array clock rate in MHz

f_{s1} = Average dedicated array clock rate in MHz

f_{s2} = Average dedicated I/O clock rate in MHz

ACT 3 Timing Model

f _{MAX}	Flip-Flop Clock Frequency		250		200		150		125		100	MHz

Notes:

1. VCC = 3.0 V for 3.3 V specifications.
2. For dual-module macros, use t_{PD} + t_{RD1} + t_{PDn} + t_{CO} + t_{RD1} + t_{PDn} or t_{PD1} + t_{RD1} + t_{SUD}, whichever is appropriate.
3. The –2 and –3 speed grades have been discontinued. Refer to PDN 0104, PDN 0203, PDN 0604, and PDN 1004 at <http://www.microsemi.com/soc/support/notifications/default.aspx#pdn>.
4. Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual worst-case performance. Post-route timing is based on actual routing delay measurements performed on the device prior to shipment.

t _{SUD}	Flip-Flop Data Input Setup	0.5		0.6		0.7		0.8		0.8		ns
t _{HD}	Flip-Flop Data Input Hold	0.0		0.0		0.0		0.0		0.0		ns
t _{SUD}	Latch Data Input Setup	0.5		0.6		0.7		0.8		0.8		ns
t _{HD}	Latch Data Input Hold	0.0		0.0		0.0		0.0		0.0		ns
t _{WASYN}	Asynchronous Pulse Width	1.9		2.4		3.2		3.8		4.8		ns
t _{WCLKA}	Flip-Flop Clock Pulse Width	1.9		2.4		3.2		3.8		4.8		ns
t _A	Flip-Flop Clock Input Period	4.0		5.0		6.8		8.0		10.0		ns
f _{MAX}	Flip-Flop Clock Frequency		250		200		150		125		100	MHz

Notes:

1. VCC = 3.0 V for 3.3 V specifications.
2. For dual-module macros, use t_{PD} + t_{RD1} + t_{PDn} + t_{CO} + t_{RD1} + t_{PDn} or t_{PD1} + t_{RD1} + t_{SUD}, whichever is appropriate.
3. The –2 and –3 speed grades have been discontinued. Refer to PDN 0104, PDN 0203, PDN 0604, and PDN 1004 at <http://www.microsemi.com/soc/support/notifications/default.aspx#pdn>.
4. Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual worst-case performance. Post-route timing is based on actual routing delay measurements performed on the device prior to shipment.

A14100A, A14V100A Timing Characteristics
