Welcome to <u>E-XFL.COM</u>

#### Understanding <u>Embedded - FPGAs (Field</u> <u>Programmable Gate Array)</u>

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

#### **Applications of Embedded - FPGAs**

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Obsolete
Number of LABs/CLBs	624
Number of Logic Elements/Cells	4992
Total RAM Bits	49152
Number of I/O	338
Number of Gates	257000
Voltage - Supply	2.375V ~ 2.625V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 70°C (TA)
Package / Case	484-BBGA
Supplier Device Package	484-FBGA (23x23)
Purchase URL	https://www.e-xfl.com/product-detail/intel/epf10k100efc484-2n

Email: info@E-XFL.COM

Address: Room A, 16/F, Full Win Commercial Centre, 573 Nathan Road, Mongkok, Hong Kong

For more information on FLEX device configuration, see the following documents:

- Configuration Devices for APEX & FLEX Devices Data Sheet
- BitBlaster Serial Download Cable Data Sheet
- ByteBlasterMV Parallel Port Download Cable Data Sheet
- MasterBlaster Download Cable Data Sheet
- Application Note 116 (Configuring APEX 20K, FLEX 10K, & FLEX 6000 Devices)

FLEX 10KE devices are supported by the Altera development systems, which are integrated packages that offer schematic, text (including AHDL), and waveform design entry, compilation and logic synthesis, full simulation and worst-case timing analysis, and device configuration. The Altera software provides EDIF 2 0 0 and 3 0 0, LPM, VHDL, Verilog HDL, and other interfaces for additional design entry and simulation support from other industry-standard PC- and UNIX workstation-based EDA tools.

The Altera software works easily with common gate array EDA tools for synthesis and simulation. For example, the Altera software can generate Verilog HDL files for simulation with tools such as Cadence Verilog-XL. Additionally, the Altera software contains EDA libraries that use devicespecific features such as carry chains, which are used for fast counter and arithmetic functions. For instance, the Synopsys Design Compiler library supplied with the Altera development system includes DesignWare functions that are optimized for the FLEX 10KE architecture.

The Altera development system runs on Windows-based PCs and Sun SPARCstation, and HP 9000 Series 700/800.

See the MAX+PLUS II Programmable Logic Development System & Software Data Sheet and the Quartus Programmable Logic Development System & Software Data Sheet for more information.

#### Figure 4. FLEX 10KE Device in Single-Port RAM Mode

#### Note:

(1) EPF10K30E, EPF10K50E, and EPF10K50S devices have 88 EAB local interconnect channels; EPF10K100E, EPF10K130E, EPF10K200E, and EPF10K200S devices have 104 EAB local interconnect channels.

EABs can be used to implement synchronous RAM, which is easier to use than asynchronous RAM. A circuit using asynchronous RAM must generate the RAM write enable signal, while ensuring that its data and address signals meet setup and hold time specifications relative to the write enable signal. In contrast, the EAB's synchronous RAM generates its own write enable signal and is self-timed with respect to the input or write clock. A circuit using the EAB's self-timed RAM must only meet the setup and hold time specifications of the global clock. The programmable flipflop in the LE can be configured for D, T, JK, or SR operation. The clock, clear, and preset control signals on the flipflop can be driven by global signals, general-purpose I/O pins, or any internal logic. For combinatorial functions, the flipflop is bypassed and the output of the LUT drives the output of the LE.

The LE has two outputs that drive the interconnect: one drives the local interconnect and the other drives either the row or column FastTrack Interconnect routing structure. The two outputs can be controlled independently. For example, the LUT can drive one output while the register drives the other output. This feature, called register packing, can improve LE utilization because the register and the LUT can be used for unrelated functions.

The FLEX 10KE architecture provides two types of dedicated high-speed data paths that connect adjacent LEs without using local interconnect paths: carry chains and cascade chains. The carry chain supports high-speed counters and adders and the cascade chain implements wide-input functions with minimum delay. Carry and cascade chains connect all LEs in a LAB as well as all LABs in the same row. Intensive use of carry and cascade chains can reduce routing flexibility. Therefore, the use of these chains should be limited to speed-critical portions of a design.

# Carry Chain

The carry chain provides a very fast (as low as 0.2 ns) carry-forward function between LEs. The carry-in signal from a lower-order bit drives forward into the higher-order bit via the carry chain, and feeds into both the LUT and the next portion of the carry chain. This feature allows the FLEX 10KE architecture to implement high-speed counters, adders, and comparators of arbitrary width efficiently. Carry chain logic can be created automatically by the Altera Compiler during design processing, or manually by the designer during design entry. Parameterized functions such as LPM and DesignWare functions automatically take advantage of carry chains.

Carry chains longer than eight LEs are automatically implemented by linking LABs together. For enhanced fitting, a long carry chain skips alternate LABs in a row. A carry chain longer than one LAB skips either from even-numbered LAB to even-numbered LAB, or from oddnumbered LAB to odd-numbered LAB. For example, the last LE of the first LAB in a row carries to the first LE of the third LAB in the row. The carry chain does not cross the EAB at the middle of the row. For instance, in the EPF10K50E device, the carry chain stops at the eighteenth LAB and a new one begins at the nineteenth LAB.

# Figure 11. FLEX 10KE LE Operating Modes

#### **Clearable Counter Mode**

#### Normal Mode

The normal mode is suitable for general logic applications and wide decoding functions that can take advantage of a cascade chain. In normal mode, four data inputs from the LAB local interconnect and the carry-in are inputs to a four-input LUT. The Altera Compiler automatically selects the carry-in or the DATA3 signal as one of the inputs to the LUT. The LUT output can be combined with the cascade-in signal to form a cascade chain through the cascade-out signal. Either the register or the LUT can be used to drive both the local interconnect and the FastTrack Interconnect routing structure at the same time.

The LUT and the register in the LE can be used independently (register packing). To support register packing, the LE has two outputs; one drives the local interconnect, and the other drives the FastTrack Interconnect routing structure. The DATA4 signal can drive the register directly, allowing the LUT to compute a function that is independent of the registered signal; a three-input function can be computed in the LUT, and a fourth independent signal can be registered. Alternatively, a four-input function can be generated, and one of the inputs to this function can be used to drive the register. The register in a packed LE can still use the clock enable, clear, and preset signals in the LE. In a packed LE, the register can drive the FastTrack Interconnect routing structure while the LUT drives the local interconnect, or vice versa.

# Arithmetic Mode

The arithmetic mode offers 2 three-input LUTs that are ideal for implementing adders, accumulators, and comparators. One LUT computes a three-input function; the other generates a carry output. As shown in Figure 11 on page 22, the first LUT uses the carry-in signal and two data inputs from the LAB local interconnect to generate a combinatorial or registered output. For example, in an adder, this output is the sum of three signals: a, b, and carry-in. The second LUT uses the same three signals to generate a carry-out signal, thereby creating a carry chain. The arithmetic mode also supports simultaneous use of the cascade chain.

# **Up/Down Counter Mode**

The up/down counter mode offers counter enable, clock enable, synchronous up/down control, and data loading options. These control signals are generated by the data inputs from the LAB local interconnect, the carry-in signal, and output feedback from the programmable register. Use 2 three-input LUTs: one generates the counter data, and the other generates the fast carry bit. A 2-to-1 multiplexer provides synchronous loading. Data can also be loaded asynchronously with the clear and preset register control signals without using the LUT resources.

#### **Asynchronous Clear**

The flipflop can be cleared by either LABCTRL1 or LABCTRL2. In this mode, the preset signal is tied to VCC to deactivate it.

#### **Asynchronous Preset**

An asynchronous preset is implemented as an asynchronous load, or with an asynchronous clear. If DATA3 is tied to VCC, asserting LABCTRL1 asynchronously loads a one into the register. Alternatively, the Altera software can provide preset control by using the clear and inverting the input and output of the register. Inversion control is available for the inputs to both LEs and IOEs. Therefore, if a register is preset by only one of the two LABCTRL signals, the DATA3 input is not needed and can be used for one of the LE operating modes.

# **Asynchronous Preset & Clear**

When implementing asynchronous clear and preset, LABCTRL1 controls the preset and LABCTRL2 controls the clear. DATA3 is tied to VCC, so that asserting LABCTRL1 asynchronously loads a one into the register, effectively presetting the register. Asserting LABCTRL2 clears the register.

# Asynchronous Load with Clear

When implementing an asynchronous load in conjunction with the clear, LABCTRL1 implements the asynchronous load of DATA3 by controlling the register preset and clear. LABCTRL2 implements the clear by controlling the register clear; LABCTRL2 does not have to feed the preset circuits.

# **Asynchronous Load with Preset**

When implementing an asynchronous load in conjunction with preset, the Altera software provides preset control by using the clear and inverting the input and output of the register. Asserting LABCTRL2 presets the register, while asserting LABCTRL1 loads the register. The Altera software inverts the signal that drives DATA3 to account for the inversion of the register's output.

# Asynchronous Load without Preset or Clear

When implementing an asynchronous load without preset or clear, LABCTRL1 implements the asynchronous load of DATA3 by controlling the register preset and clear.

Symbol	Parameter	Condition	Min	Тур	Max	Unit
t <sub>R</sub>	Input rise time				5	ns
t <sub>F</sub>	Input fall time				5	ns
t <sub>INDUTY</sub>	Input duty cycle		40		60	%
f <sub>CLK1</sub>	Input clock frequency (ClockBoost clock multiplication factor equals 1)		25		75	MHz
f <sub>CLK2</sub>	Input clock frequency (ClockBoost clock multiplication factor equals 2)		16		37.5	MHz
f <sub>CLKDEV</sub>	Input deviation from user specification in the MAX+PLUS II software (1)				25,000 (2)	PPM
t <sub>INCLKSTB</sub>	Input clock stability (measured between adjacent clocks)				100	ps
t <sub>LOCK</sub>	Time required for ClockLock or ClockBoost to acquire lock (3)				10	μs
t <sub>JITTER</sub>	Jitter on ClockLock or ClockBoost-	$t_{INCLKSTB} < 100$			250	ps
	generated clock (4)	$t_{INCLKSTB} < 50$			200 (4)	ps
toutduty	Duty cycle for ClockLock or ClockBoost-generated clock		40	50	60	%

#### Notes to tables:

- (1) To implement the ClockLock and ClockBoost circuitry with the MAX+PLUS II software, designers must specify the input frequency. The Altera software tunes the PLL in the ClockLock and ClockBoost circuitry to this frequency. The f<sub>CLKDEV</sub> parameter specifies how much the incoming clock can differ from the specified frequency during device operation. Simulation does not reflect this parameter.
- (2) Twenty-five thousand parts per million (PPM) equates to 2.5% of input clock period.
- (3) During device configuration, the ClockLock and ClockBoost circuitry is configured before the rest of the device. If the incoming clock is supplied during configuration, the ClockLock and ClockBoost circuitry locks during configuration because the t<sub>LOCK</sub> value is less than the time required for configuration.
- (4) The t<sub>ITTER</sub> specification is measured under long-term observation. The maximum value for t<sub>ITTER</sub> is 200 ps if t<sub>INCLKSTB</sub> is lower than 50 ps.

# I/O Configuration

This section discusses the peripheral component interconnect (PCI) pull-up clamping diode option, slew-rate control, open-drain output option, and MultiVolt I/O interface for FLEX 10KE devices. The PCI pull-up clamping diode, slew-rate control, and open-drain output options are controlled pin-by-pin via Altera software logic options. The MultiVolt I/O interface is controlled by connecting  $V_{CCIO}$  to a different voltage than  $V_{CCINT}$ . Its effect can be simulated in the Altera software via the **Global Project Device Options** dialog box (Assign menu).

Table 17. 32-Bit IDCODE for FLEX 10KE Devices     Note (1)

#### Notes:

(1) The most significant bit (MSB) is on the left.

(2) The least significant bit (LSB) for all JTAG IDCODEs is 1.

FLEX 10KE devices include weak pull-up resistors on the JTAG pins.

For more information, see the following documents:

- Application Note 39 (IEEE Std. 1149.1 (JTAG) Boundary-Scan Testing in Altera Devices)
- BitBlaster Serial Download Cable Data Sheet
- ByteBlasterMV Parallel Port Download Cable Data Sheet
- Jam Programming & Test Language Specification

Figure 20 shows the timing requirements for the JTAG signals.

Figure 20. FLEX 10KE JTAG Waveforms

# Table 18 shows the timing parameters and values for FLEX 10KE devices.

Sumbol	Parameter	Min	Max	Unit
Symbol	Parameter	IVIIII	IVIAX	Unit
t <sub>JCP</sub>	TCK clock period	100		ns

t <sub>JSXZ</sub>	Update register valid output to high impedance		35	ns

Figure 22 shows the required relationship between  $V_{CCIO}$  and  $V_{CCINT}$  for 3.3-V PCI compliance.

Figure 23 shows the typical output drive characteristics of FLEX 10KE devices with 3.3-V and 2.5-V V<sub>CCIO</sub>. The output driver is compliant to the 3.3-V *PCI Local Bus Specification*, *Revision 2.2* (when VCCIO pins are connected to 3.3 V). FLEX 10KE devices with a -1 speed grade also comply with the drive strength requirements of the *PCI Local Bus Specification*, *Revision 2.2* (when VCCINT pins are powered with a minimum supply of 2.375 V, and VCCIO pins are connected to 3.3 V). Therefore, these devices can be used in open 5.0-V PCI systems.

#### **Altera Corporation**

Timing simulation and delay prediction are available with the Altera Simulator and Timing Analyzer, or with industry-standard EDA tools. The Simulator offers both pre-synthesis functional simulation to evaluate logic design accuracy and post-synthesis timing simulation with 0.1-ns resolution. The Timing Analyzer provides point-to-point timing delay information, setup and hold time analysis, and device-wide performance analysis.

Figure 24 shows the overall timing model, which maps the possible paths to and from the various elements of the FLEX 10KE device.

Figures 25 through 28 show the delays that correspond to various paths and functions within the LE, IOE, EAB, and bidirectional timing models.

t <sub>ZXBIDIR</sub>	Synchronous IOE output buffer enable delay, slow slew rate= off	C1 = 35 pF				

#### Notes to tables:

- (1) Microparameters are timing delays contributed by individual architectural elements. These parameters cannot be measured explicitly.
- (2) Operating conditions: VCCIO =  $3.3 \text{ V} \pm 10\%$  for commercial or industrial use.
- (3) Operating conditions: VCCIO = 2.5 V ±5% for commercial or industrial use in EPF10K30E, EPF10K50S, EPF10K100E, EPF10K130E, and EPF10K200S devices.
- (4) Operating conditions: VCCIO = 3.3 V.
- (5) Because the RAM in the EAB is self-timed, this parameter can be ignored when the WE signal is registered.
- (6) EAB macroparameters are internal parameters that can simplify predicting the behavior of an EAB at its boundary; these parameters are calculated by summing selected microparameters.
- (7) These parameters are worst-case values for typical applications. Post-compilation timing simulation and timing analysis are required to determine actual worst-case performance.
- (8) Contact Altera Applications for test circuit specifications and test conditions.
- (9) This timing parameter is sample-tested only.
- (10) This parameter is measured with the measurement and test conditions, including load, specified in the PCI Local Bus Specification, revision 2.2.

Figures 29 and 30 show the asynchronous and synchronous timing waveforms, respectively, or the EAB macroparameters in Tables 26 and 27.

Power Consumption	The supply power (P) for FLEX 10KE devices can be calculated with the following equation:	
	$P = P_{INT} + P_{IO} = (I_{CCSTANDBY} + I_{CCACTIVE}) \times V_{CC} + P_{IO}$	
	The $I_{CCACTIVE}$ value depends on the switching frequency and the application logic. This value is calculated based on the amount of current that each LE typically consumes. The $P_{IO}$ value, which depends on the device output load characteristics and switching frequency, can be calculated using the guidelines given in <i>Application Note 74 (Evaluating Power for Altera Devices)</i> .	
	Compared to the rest of the device, the embedded array consumes a negligible amount of power. Therefore, the embedded array can be ignored when calculating supply current.	
	The $I_{\mbox{\scriptsize CCACTIVE}}$ value can be calculated with the following equation:	
	$I_{CCACTIVE} = \mathbf{K} \times \mathbf{f}_{\mathbf{MAX}} \times \mathbf{N} \times \mathbf{tog}_{\mathbf{LC}} \times \frac{\mu \mathbf{A}}{\mathbf{MHz} \times \mathbf{LE}}$	
	Where:	
	<ul> <li>f<sub>MAX</sub> = Maximum operating frequency in MHz</li> <li>N = Total number of LEs used in the device</li> <li>tog<sub>LC</sub> = Average percent of LEs toggling at each clock (typically 12.5%)</li> <li>K = Constant</li> </ul>	
	Table 80 provides the constant (K) values for FLEX 10KE devices.	
	Table 80. FLEX 10KE K Constant Values	
	Device	K Value
	EPF10K30E	4.5
	EPF10K50E	4.8
	EPF10K50S	4.5
	EPF10K100E	4.5
	EPF10K130E	4.6
	EPF10K200E	4.8

EPF10K200S

This calculation provides an  $I_{CC}$  estimate based on typical conditions with no output load. The actual  $I_{CC}$  should be verified during operation because this measurement is sensitive to the actual pattern in the device and the environmental operating conditions.

4.6

Device Pin-Outs	See the Altera web site (http://www.altera.com) or the Altera Digital Library for pin-out information.	
Revision History	The information contained in the <i>FLEX 10KE Embedded Programmable Logic Data Sheet</i> version 2.5 supersedes information published in previous versions.	
	Version 2.5	
	The following changes were made to the <i>FLEX 10KE Embedded Programmable Logic Data Sheet</i> version 2.5:	
	<ul> <li><i>Note (1)</i> added to Figure 23.</li> <li>Text added to "I/O Element" section on page 34.</li> <li>Updated Table 22.</li> </ul>	
	Version 2.4 The following changes were made to the FLEX 10KE Embedded	

Programmable Logic Data Sheet version 2.4: updated text on page 34 and page 63.
