

Welcome to [E-XFL.COM](https://www.e-xfl.com)

What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "[Embedded - Microcontrollers](#)"

Details

Product Status	Active
Core Processor	PIC
Core Size	16-Bit
Speed	32MHz
Connectivity	I ² C, IrDA, LINbus, PMP/PSP, SmartCard, SPI, UART/USART
Peripherals	AES, Brown-out Detect/Reset, DMA, I ² S, HLVD, POR, PWM, WDT
Number of I/O	34
Program Memory Size	128KB (43K x 24)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	8K x 8
Voltage - Supply (Vcc/Vdd)	2V ~ 3.6V
Data Converters	A/D 12x10b/12b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	44-VQFN Exposed Pad
Supplier Device Package	44-QFN (8x8)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic24fj128gb204t-i-ml

TABLE 4-35: EDS MEMORY ADDRESS WITH DIFFERENT PAGES AND ADDRESSES

DSRPAG (Data Space Read Register)	DSWPAG (Data Space Write Register)	Source/Destination Address while Indirect Addressing	24-Bit EA Pointing to EDS	Comment
x ⁽¹⁾	x ⁽¹⁾	0000h to 1FFFh	000000h to 001FFFh	Near Data Space ⁽²⁾
		2000h to 7FFFh	002000h to 007FFFh	
001h	001h	8000h to FFFFh	008000h to 00FFFEh	EPMP Memory Space
002h	002h		010000h to 017FFEh	
003h	003h		018000h to 0187FEh	
•	•		•	
•	•		•	
•	•		•	
•	•		•	
1FFh	1FFh		FF8000h to FFFFFEh	
000h	000h		Invalid Address	Address Error Trap ⁽³⁾

Note 1: If the source/destination address is below 8000h, the DSRPAG and DSWPAG registers are not considered.

2: This Data Space can also be accessed by Direct Addressing.

3: When the source/destination address is above 8000h and DSRPAG/DSWPAG are '0', an address error trap will occur.

4.2.6 SOFTWARE STACK

Apart from its use as a Working register, the W15 register in PIC24F devices is also used as a Software Stack Pointer (SSP). The pointer always points to the first available free word and grows from lower to higher addresses. It decrements for stack pops and post-increments for stack pushes, as shown in Figure 4-7. Note that for a PC push during any CALL instruction, the MSB of the PC is zero-extended before the push, ensuring that the MSB is always clear.

Note: A PC push during exception processing will concatenate the SRL Register to the MSB of the PC prior to the push.

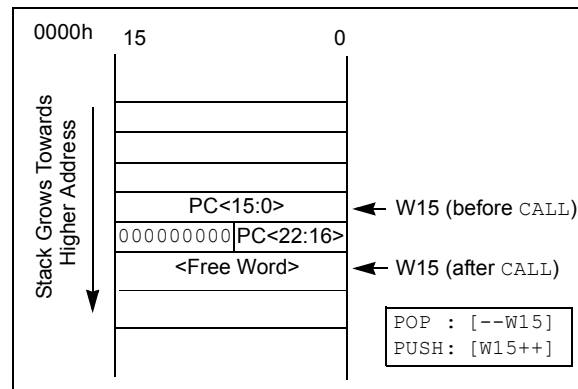

The Stack Pointer Limit Value (SPLIM) register, associated with the Stack Pointer, sets an upper address boundary for the stack. SPLIM is uninitialized at Reset. As is the case for the Stack Pointer, SPLIM<0> is forced to '0' as all stack operations must be word-aligned. Whenever an EA is generated using W15 as a Source or Destination Pointer, the resulting address is compared with the value in SPLIM. If the contents of the Stack Pointer (W15) and the SPLIM register are equal, and a push operation is performed, a stack error trap will not occur. The stack error trap will occur on a subsequent push operation. Thus, for

example, if it is desirable to cause a stack error trap when the stack grows beyond address, 2000h in RAM, initialize the SPLIM with the value, 1FFEh.

Similarly, a Stack Pointer underflow (stack error) trap is generated when the Stack Pointer address is found to be less than 0800h. This prevents the stack from interfering with the SFR space.

A write to the SPLIM register should not be immediately followed by an indirect read operation using W15.

 1 = Upon waking from Deep Sleep, I/O pins maintain their states previous to the Deep Sleep entry
 0 = Releases I/O pins from their state previous to Deep Sleep entry, and allows their respective TRISx and LATx bits to control their states

- Note 1:** All register bits are reset only in the case of a POR event outside of Deep Sleep mode.
- Note 2:** Unlike all other events, a Deep Sleep BOR event will NOT cause a wake-up from Deep Sleep; this re-arms the POR.

PIC24FJ128GB204 FAMILY

11.1.1 I/O PORT WRITE/READ TIMING

One instruction cycle is required between a port direction change or port write operation and a read operation of the same port. Typically, this instruction would be a `NOP`.

11.1.2 OPEN-DRAIN CONFIGURATION

In addition to the `PORTx`, `LATx` and `TRISx` registers for data control, each port pin can also be individually configured for either a digital or open-drain output. This is controlled by the Open-Drain Control register, `ODCx`, associated with each port. Setting any of the bits configures the corresponding pin to act as an open-drain output.

The open-drain feature allows the generation of outputs higher than V_{DD} (e.g., 5V), on any desired digital only pins, by using external pull-up resistors. The maximum open-drain voltage allowed is the same as the maximum V_{IH} specification.

11.2 Configuring Analog Port Pins (ANSx)

The `ANSx` and `TRISx` registers control the operation of the pins with analog function. Each port pin with analog function is associated with one of the `ANSx` bits (see [Register 11-1](#) through [Register 11-3](#)), which decides if the pin function should be analog or digital. Refer to [Table 11-1](#) for detailed behavior of the pin for different `ANSx` and `TRISx` bit settings.

When reading the `PORTx` register, all pins configured as analog input channels will read as cleared (a low level).

11.2.1 ANALOG INPUT PINS AND VOLTAGE CONSIDERATIONS

The voltage tolerance of pins used as device inputs is dependent on the pin's input function. Most input pins are able to handle DC voltages of up to 5.5V, a level typical for digital logic circuits. However, several pins can only tolerate voltages up to V_{DD} . Voltage excursions beyond V_{DD} on these pins should always be avoided.

[Table 11-2](#) summarizes the different voltage tolerances. For more information, refer to [Section 33.0 "Electrical Characteristics"](#) for more details.

TABLE 11-1: CONFIGURING ANALOG/DIGITAL FUNCTION OF AN I/O PIN

Pin Function	ANSx Setting	TRISx Setting	Comments
Analog Input	1	1	It is recommended to keep <code>ANSx</code> = 1.
Analog Output	1	1	It is recommended to keep <code>ANSx</code> = 1.
Digital Input	0	1	Firmware must wait at least one instruction cycle after configuring a pin as a digital input before a valid input value can be read.
Digital Output	0	0	Make sure to disable the analog output function on the pin if any is present.

TABLE 11-2: INPUT VOLTAGE LEVELS FOR PORT OR PIN TOLERATED DESCRIPTION INPUT

Port or Pin	Tolerated Input	Description
<code>PORTA<10:7,4></code> ⁽¹⁾	5.5V	Tolerates input levels above V_{DD} ; useful for most standard logic.
<code>PORTB<11:10,8,4></code>		
<code>PORTC<9:3></code> ⁽¹⁾		
<code>PORTA<3:0></code>	V_{DD}	Only V_{DD} input levels are tolerated.
<code>PORTB<15:13,9,3:0></code>		
<code>PORTC<2:0></code> ⁽¹⁾		

Note 1: Not all of these pins are implemented in 28-pin devices. Refer to [Section 1.0 "Device Overview"](#) for a complete description of port pin implementation.

bit 1	OERR : Receive Buffer Overrun Error Status bit (clear/read-only) 1 = Receive buffer has overflowed 0 = Receive buffer has not overflowed (clearing a previously set OERR bit (1 → 0 transition); will reset the receive buffer and the RSR to the empty state)
bit 0	URXDA : UARTx Receive Buffer Data Available bit (read-only) 1 = Receive buffer has data, at least one more character can be read 0 = Receive buffer is empty

- Note 1:** The value of this bit only affects the transmit properties of the module when the IrDA[®] encoder is enabled (IREN = 1).
- 2:** If UARTEN = 1, the peripheral inputs and outputs must be configured to an available RPN/RPIN pin. For more information, see [Section 11.4 “Peripheral Pin Select \(PPS\)”](#).

PIC24FJ128GB204 FAMILY

19.1 Hardware Configuration

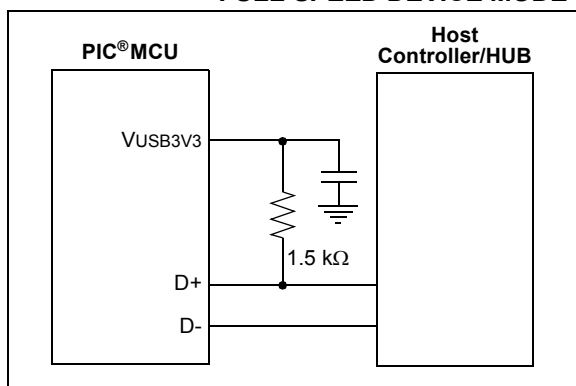

19.1.1 DEVICE MODE

19.1.1.1 D+ Pull-up Resistor

PIC24FJ128GB204 family devices have a built-in 1.5 k Ω resistor on the D+ line that is available when the microcontroller is operating in Device mode. This is used to signal an external host that the device is operating in Full-Speed Device mode. It is engaged by setting the USBEN bit (U1CON<0>). If the OTGEN bit (U1OTGCON<2>) is set, then the D+ pull-up is enabled through the DPPULUP bit (U1OTGCON<7>).

Alternatively, an external resistor may be used on D+, as shown in Figure 19-2.

FIGURE 19-2: EXTERNAL PULL-UP FOR FULL-SPEED DEVICE MODE

19.1.1.2 Power Modes

Many USB applications will likely have several different sets of power requirements and configuration. The most common power modes encountered are:

- Bus Power Only mode
- Self-Power Only mode
- Dual Power with Self-Power Dominance mode

Bus Power Only mode (Figure 19-3) is effectively the simplest method. All power for the application is drawn from the USB.

To meet the inrush current requirements of the “USB 2.0 Specification”, the total effective capacitance appearing across VBUS and ground must be no more than 10 μ F.

In the USB Suspend mode, devices must consume no more than 2.5 mA from the 5V VBUS line of the USB cable. During the USB Suspend mode, the D+ or D- pull-up resistor must remain active, which will consume some of the allowed suspend current.

In Self-Power Only mode (Figure 19-4), the USB application provides its own power, with very little power being pulled from the USB. Note that an attach indication is added to indicate when the USB has been connected and the host is actively powering VBUS.

To meet compliance specifications, the USB module (and the D+ or D- pull-up resistor) should not be enabled until the host actively drives VBUS high. One of the 5.5V tolerant I/O pins may be used for this purpose.

The application should never source any current onto the 5V VBUS pin of the USB cable.

The Dual Power with Self-Power Dominance mode (Figure 19-5) allows the application to use internal power primarily, but switch to power from the USB when no internal power is available. Dual power devices must also meet all of the special requirements for inrush current and Suspend mode current previously described, and must not enable the USB module until VBUS is driven high.

FIGURE 19-3: BUS POWER ONLY

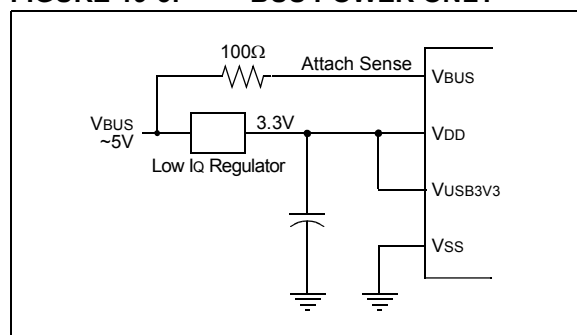

FIGURE 19-4: SELF-POWER ONLY

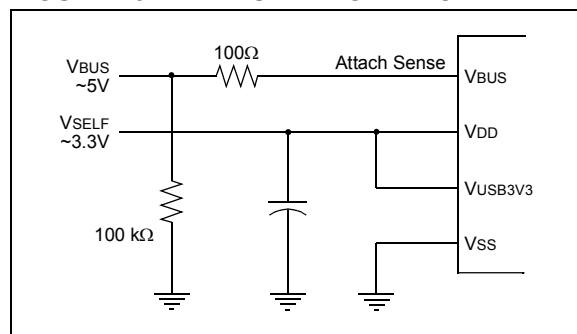

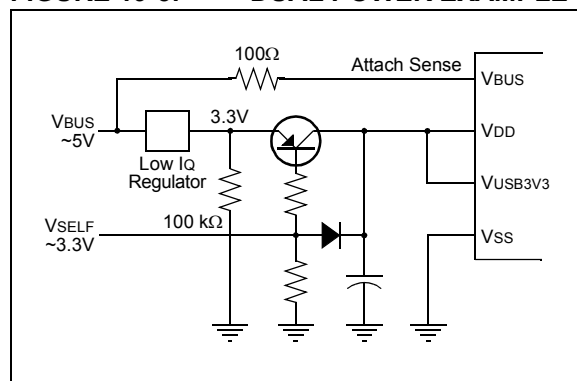

FIGURE 19-5: DUAL POWER EXAMPLE

PIC24FJ128GB204 FAMILY

19.4.2 RECEIVING AN IN TOKEN IN DEVICE MODE

1. Attach to a USB host and enumerate as described in Chapter 9 of the *“USB 2.0 Specification”*.
2. Create a data buffer and populate it with the data to send to the host.
3. In the appropriate (Even or Odd) TX BD for the desired endpoint:
 - a) Set up the status register (BDnSTAT) with the correct data toggle (DATA0/1) value and the byte count of the data buffer.
 - b) Set up the address register (BDnADR) with the starting address of the data buffer.
 - c) Set the UOWN bit of the status register to ‘1’.
4. When the USB module receives an IN token, it automatically transmits the data in the buffer. Upon completion, the module updates the status register (BDnSTAT) and sets the Transfer Done Interrupt Flag, TRNIF (U1IR<3>).

19.4.3 RECEIVING AN OUT TOKEN IN DEVICE MODE

1. Attach to a USB host and enumerate as described in Chapter 9 of the *“USB 2.0 Specification”*.
2. Create a data buffer with the amount of data you are expecting from the host.
3. In the appropriate (Even or Odd) TX BD for the desired endpoint:
 - a) Set up the status register (BDnSTAT) with the correct data toggle (DATA0/1) value and the byte count of the data buffer.
 - b) Set up the address register (BDnADR) with the starting address of the data buffer.
 - c) Set the UOWN bit of the status register to ‘1’.
4. When the USB module receives an OUT token, it automatically receives the data sent by the host to the buffer. Upon completion, the module updates the status register (BDnSTAT) and sets the Transfer Done Interrupt Flag, TRNIF (U1IR<3>).

19.5 Host Mode Operation

The following sections describe how to perform common Host mode tasks. In Host mode, USB transfers are invoked explicitly by the host software. The host software is responsible for the Acknowledge portion of the transfer. Also, all transfers are performed using the USB Endpoint 0 Control register (U1EP0) and Buffer Descriptors.

19.5.1 ENABLE HOST MODE AND DISCOVER A CONNECTED DEVICE

1. Enable Host mode by setting the HOSTEN bit (U1CON<3>). This causes the Host mode control bits in other USB OTG registers to become available.
2. Enable the D+ and D- pull-down resistors by setting the DPPULDOWN and DMPULDOWN bits (U1OTGCON<5:4>). Disable the D+ and D-pull-up resistors by clearing the DPPULUP and DMPULUP bits (U1OTGCON<7:6>).
3. At this point, Start-of-Frame (SOF) generation begins with the SOF counter loaded with 12,000. Eliminate noise on the USB by clearing the SOFEN bit (U1CON<0>) to disable Start-of-Frame packet generation.
4. Enable the device attached interrupt by setting the ATTACHIE bit (U1IE<6>).
5. Wait for the device attached interrupt (U1IR<6> = 1). This is signaled by the USB device changing the state of D+ or D- from ‘0’ to ‘1’ (SE0 to J-state). After it occurs, wait 100 ms for the device power to stabilize.
6. Check the state of the JSTATE and SE0 bits in U1CON. If the JSTATE bit (U1CON<7>) is ‘0’, the connecting device is low speed. If the connecting device is low speed, set the LSPDEN and LSPD bits (U1ADDR<7> and U1EP0<7>, respectively) to enable low-speed operation.
7. Reset the USB device by setting the USBRST bit (U1CON<4>) for at least 50 ms, sending Reset signaling on the bus. After 50 ms, terminate the Reset by clearing USBRST.
8. In order to keep the connected device from going into suspend, enable the SOF packet generation by setting the SOFEN bit.
9. Wait 10 ms for the device to recover from Reset.
10. Perform enumeration as described by Chapter 9 of the *“USB 2.0 Specification”*.

PIC24FJ128GB204 FAMILY

19.5.3 SEND A FULL-SPEED BULK DATA TRANSFER TO A TARGET DEVICE

1. Follow the procedure described in [Section 19.5.1 “Enable Host Mode and Discover a Connected Device”](#) and [Section 19.5.2 “Complete a Control Transaction to a Connected Device”](#) to discover and configure a device.
2. To enable transmit and receive transfers with handshaking enabled, write 1Dh to U1EP0. If the target device is a low-speed device, also set the LSPD (U1EP0<7>) bit. If you want the hardware to automatically retry indefinitely, if the target device asserts a NAK on the transfer, clear the Retry Disable bit, RETRYDIS (U1EP0<6>).
3. Set up the BD for the current (Even or Odd) TX EP0 to transfer up to 64 bytes.
4. Set the USB device address of the target device in the USB Address register (U1ADDR<6:0>).
5. Write an OUT token to the desired endpoint to U1TOK. This triggers the module's transmit state machines to begin transmitting the token and the data.
6. Wait for the Transfer Done Interrupt Flag, TRNIF. This indicates that the BD has been released back to the microprocessor and the transfer has completed. If the Retry Disable bit (RETRYDIS) is set, the handshake (ACK, NAK, STALL or ERROR (0Fh)) is returned in the BD PID field. If a STALL interrupt occurs, the pending packet must be dequeued and the error condition in the target device cleared. If a detach interrupt occurs (SE0 for more than 2.5 μ s), then the target has detached (U1IR<0> is set).
7. Once the Transfer Done Interrupt Flag occurs (TRNIF is set), the BD can be examined and the next data packet queued by returning to Step 2.

Note: USB speed, transceiver and pull-ups should only be configured during the module setup phase. It is not recommended to change these settings while the module is enabled.

19.6 OTG Operation

19.6.1 SESSION REQUEST PROTOCOL (SRP)

An OTG A-device may decide to power down the VBUS supply when it is not using the USB link through the Session Request Protocol (SRP). Software may do this by clearing VBUSON (U1OTGCON<3>). When the VBUS supply is powered down, the A-device is said to have ended a USB session.

An OTG A-device or embedded host may repower the VBUS supply at any time (initiate a new session). An OTG B-device may also request that the OTG A-device repower the VBUS supply (initiate a new session). This is accomplished via the Session Request Protocol (SRP).

Prior to requesting a new session, the B-device must first check that the previous session has definitely ended. To do this, the B-device must check for two conditions:

1. VBUS supply is below the session valid voltage.
2. Both D+ and D- have been low for at least 2 ms.

The B-device will be notified of Condition 1 by the SESENDIF (U1OTGIR<2>) interrupt. Software will have to manually check for Condition 2.

Note: When the A-device powers down the VBUS supply, the B-device must disconnect its pull-up resistor from power. If the device is self-powered, it can do this by clearing DPPULUP (U1OTGCON<7>) and DMPULUP (U1OTGCON<6>).

The B-device may aid in achieving Condition 1 by discharging the VBUS supply through a resistor. Software may do this by setting VBUSDIS (U1OTGCON<0>).

After these initial conditions are met, the B-device may begin requesting the new session. The B-device begins by pulsing the D+ data line. Software should do this by setting DPPULUP (U1OTGCON<7>). The data line should be held high for 5 to 10 ms.

The B-device then proceeds by pulsing the VBUS supply. Software should do this by setting PUVBUS (U1CNFG2<4>). When an A-device detects SRP signaling (either via the ATTACHIF (U1IR<6>) interrupt or via the SESVDIF (U1OTGIR<3>) interrupt), the A-device must restore the VBUS supply by either setting VBUSON (U1OTGCON<3>) or by setting the I/O port controlling the external power source.

The B-device should not monitor the state of the VBUS supply while performing VBUS supply pulsing. When the B-device does detect that the VBUS supply has been restored (via the SESVDIF (U1OTGIR<3>) interrupt), the B-device must reconnect to the USB link by pulling up D+ or D- (via the DPPULUP or DMPULUP bits).

The A-device must complete the SRP by driving USB Reset signaling.

21.0 ENHANCED PARALLEL MASTER PORT (EPMP)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the “dsPIC33/PIC24 Family Reference Manual”, “Enhanced Parallel Master Port (EPMP)” (DS39730). The information in this data sheet supersedes the information in the FRM.

The Enhanced Parallel Master Port (EPMP) module provides a parallel, 4-bit (Master mode only) and 8-bit (Master and Slave modes) data bus interface to communicate with off-chip modules, such as memories, FIFOs, LCD controllers and other microcontrollers. This module can serve as either the master or the slave on the communication bus.

For EPMP Master modes, all external addresses are mapped into the internal Extended Data Space (EDS). This is done by allocating a region of the EDS for each chip select and then assigning each chip select to a particular external resource, such as a memory or external controller. This region should not be assigned to another device resource, such as RAM or SFRs. To perform a write or read on an external resource, the CPU simply performs a write or read within the address range assigned for the EPMP.

Key features of the EPMP module are:

- Extended Data Space (EDS) Interface allows Direct Access from the CPU
- Up to 10 Programmable Address Lines
- Up to 2 Chip Select Lines
- Up to 1 Acknowledgment Line (one per chip select)
- 4-Bit and 8-Bit Wide Data Bus
- Programmable Strobe Options (per chip select)
 - Individual Read and Write Strobes or;
 - Read/Write Strobe with Enable Strobe
- Programmable Address/Data Multiplexing
- Programmable Address Wait States
- Programmable Data Wait States (per chip select)
- Programmable Polarity on Control Signals (per chip select)
- Legacy Parallel Slave Port (PSP) Support
- Enhanced Parallel Slave Port Support
 - Address Support
 - 4-Byte Deep Auto-Incrementing Buffer

21.1 Memory Addressable in Different Modes

The memory space addressable by the device depends on the address/data multiplexing selection; it varies from 1K to 2 MB. Refer to [Table 21-1](#) for different Memory-Addressable modes.

Note 1: This bit's state is mirrored by the PGMTEST bit (CRYOTP<7>).

24.1.3 DATA SHIFT DIRECTION

The LENDIAN bit (CRCCON1<3>) is used to control the shift direction. By default, the CRC will shift data through the engine, MSb first. Setting LENDIAN (= 1) causes the CRC to shift data, LSb first. This setting allows better integration with various communication schemes and removes the overhead of reversing the bit order in software. Note that this only changes the direction the data is shifted into the engine. The result of the CRC calculation will still be a normal CRC result, not a reverse CRC result.

24.1.4 INTERRUPT OPERATION

The module generates an interrupt that is configurable by the user for either of two conditions.

If CRCISEL is '0', an interrupt is generated when the VWORD<4:0> bits make a transition from a value of '1' to '0'. If CRCISEL is '1', an interrupt will be generated after the CRC operation finishes and the module sets the CRCGO bit to '0'. Manually setting CRCGO to '0' will not generate an interrupt. Note that when an interrupt occurs, the CRC calculation would not yet be complete. The module will still need $(PLEN + 1)/2$ clock cycles, after the interrupt is generated, until the CRC calculation is finished.

24.1.5 TYPICAL OPERATION

To use the module for a typical CRC calculation:

1. Set the CRCEN bit to enable the module.
2. Configure the module for desired operation:
 - a) Program the desired polynomial using the CRCXORL and CRCXORH registers, and the PLEN<4:0> bits.
 - b) Configure the data width and shift direction using the DWIDTHx and LENDIAN bits.
 - c) Select the desired Interrupt mode using the CRCISEL bit.
3. Preload the FIFO by writing to the CRCDATL and CRCDATH registers until the CRCFUL bit is set or no data is left.

4. Clear old results by writing 00h to CRCWDATL and CRCWDATH. The CRCWDAT registers can also be left unchanged to resume a previously halted calculation.
5. Set the CRCGO bit to start calculation.
6. Write remaining data into the FIFO as space becomes available.
7. When the calculation completes, CRCGO is automatically cleared. An interrupt will be generated if CRCISEL = 1.
8. Read CRCWDATL and CRCWDATH for the result of the calculation.

There are eight registers used to control programmable CRC operation:

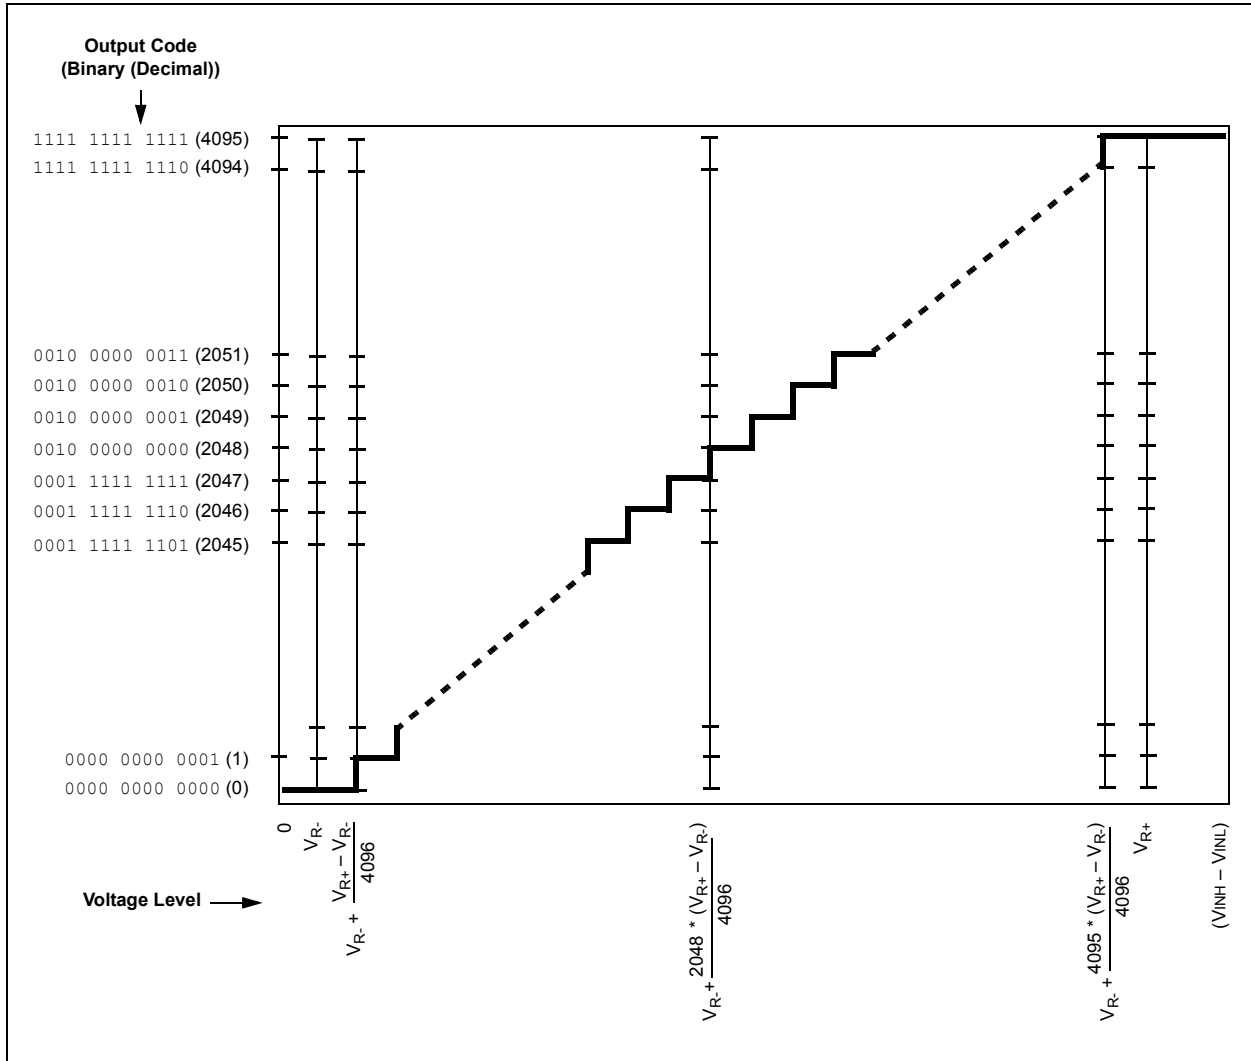

- CRCCON1
- CRCCON2
- CRCXORL
- CRCXORH
- CRCDATL
- CRCDATH
- CRCWDATL
- CRCWDATH

The CRCCON1 and CRCCON2 registers ([Register 24-1](#) and [Register 24-2](#)) control the operation of the module and configure the various settings.

The CRCXORL/H registers ([Register 24-3](#) and [Register 24-4](#)) select the polynomial terms to be used in the CRC equation. The CRCDAT and CRCWDAT registers are each register pairs that serve as buffers for the double-word input data and CRC processed output, respectively.
