
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	PIC
Core Size	16-Bit
Speed	32MHz
Connectivity	I²C, IrDA, LINbus, SmartCard, SPI, UART/USART
Peripherals	AES, Brown-out Detect/Reset, DMA, I²S, HLVD, POR, PWM, WDT
Number of I/O	20
Program Memory Size	64KB (64K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	8K x 8
Voltage - Supply (Vcc/Vdd)	2V ~ 3.6V
Data Converters	A/D 9x10b/12b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Through Hole
Package / Case	28-DIP (0.300", 7.62mm)
Supplier Device Package	28-SPDIP
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic24fj64gb202-i-sp

Analog Features

- 10/12-Bit, 12-Channel Analog-to-Digital (A/D) Converter:
  - Conversion rate of 500 ksps (10-bit), 200 ksps (12-bit)
  - Conversion available during Sleep and Idle
- Three Rail-to-Rail, Enhanced Analog Comparators with Programmable Input/Output Configuration
- Three On-Chip Programmable Voltage References
- Charge Time Measurement Unit (CTMU):
  - Used for capacitive touch sensing, up to 12 channels
  - Time measurement down to 100 ps resolution
  - Operation in Sleep mode

Peripheral Features

- Up to Five External Interrupt Sources
- Peripheral Pin Select (PPS); Allows Independent I/O Mapping of many Peripherals
- Five 16-Bit Timers/Counters with Prescaler:
  - Can be paired as 32-bit timers/counters
- Six-Channel DMA supports All Peripheral modules:
  - Minimizes CPU overhead and increases data throughput
- Six Input Capture modules, each with a Dedicated 16-Bit Timer
- Six Output Compare/PWM modules, each with a Dedicated 16-Bit Timer
- Enhanced Parallel Master/Slave Port (EPMP/EPSP)
- Hardware Real-Time Clock/Calendar (RTCC):
  - Runs in Sleep, Deep Sleep and VBAT modes
- Three 3-Wire/4-Wire SPI modules:
  - Support four Frame modes
  - Variable FIFO buffer
  - I^2S mode
  - Variable width from 2-bit to 32-bit
- Two I^2C™ modules Support Multi-Master/ Slave mode and 7-Bit/10-Bit Addressing
- Four UART modules:
  - Support RS-485, RS-232 and LIN/J2602
  - On-chip hardware encoder/decoder for IrDA®
  - Smart Card ISO 7816 support on UART1 and UART2 only:
    - T = 0 protocol with automatic error handling
    - T = 1 protocol
    - Dedicated Guard Time Counter (GTC)
    - Dedicated Waiting Time Counter (WTC)
  - Auto-wake-up on Auto-Baud Detect (ABD)
  - 4-level deep FIFO buffer
- Programmable 32-Bit Cyclic Redundancy Check (CRC) Generator
- Digital Signal Modulator provides On-Chip FSK and PSK Modulation for a Digital Signal Stream
- High-Current Sink/Source (18 mA/18 mA) on All I/O Pins
- Configurable Open-Drain Outputs on Digital I/O Pins
- 5.5V Tolerant Inputs on Most Pins

High-Performance CPU

- Modified Harvard Architecture
- Up to 16 MIPS Operation @ 32 MHz
- 8 MHz Internal Oscillator:
  - 96 MHz PLL option
  - Multiple clock divide options
  - Run-time self-calibration capability for maintaining better than ±0.20% accuracy
  - Fast start-up
- 17-Bit x 17-Bit Single-Cycle Hardware Fractional/Integer Multiplier
- 32-Bit by 16-Bit Hardware Divider
- 16 x 16-Bit Working Register Array
- C Compiler Optimized Instruction Set Architecture (ISA)
- Two Address Generation Units (AGUs) for Separate Read and Write Addressing of Data Memory

Special Microcontroller Features

- Supply Voltage Range of 2.0V to 3.6V
- Two On-Chip Voltage Regulators (1.8V and 1.2V) for Regular and Extreme Low-Power Operation
- 20,000 Erase/Write Cycle Endurance Flash Program Memory, Typical
- Flash Data Retention: 20 Years Minimum
- Self-Programmable under Software Control
- Programmable Reference Clock Output
- In-Circuit Serial Programming™ (ICSP™) and In-Circuit Emulation (ICE) via 2 Pins
- JTAG Programming and Boundary Scan Support
- Fail-Safe Clock Monitor (FSCM) Operation:
  - Detects clock failure and switches to on-chip, Low-Power RC Oscillator
- Power-on Reset (POR), Power-up Timer (PWRT) and Oscillator Start-up Timer (OST)
- Separate Brown-out Reset (BOR) and Deep Sleep Brown-out Reset (DSBOR) Circuits
- Programmable High/Low-Voltage Detect (HLVD)
- Flexible Watchdog Timer (WDT) with its Own RC Oscillator for Reliable Operation
- Standard and Ultra Low-Power Watchdog Timers (ULPW) for Reliable Operation in Standard and Deep Sleep modes

6.6.2 PROGRAMMING A SINGLE WORD OF FLASH PROGRAM MEMORY

If a Flash location has been erased, it can be programmed using Table Write instructions to write an instruction word (24-bit) into the write latch. The TBLPAG register is loaded with the 8 Most Significant Bytes (MSBs) of the Flash address. The TBLWTL and TBLWTH instructions write the desired data into the write latches and specify the lower 16 bits of the program memory address to write to. To configure the NVMCON register for a word write, set the NVMOPx bits (NVMCON<3:0>) to '0011'. The write is performed by executing the unlock sequence and setting the WR bit (see Example 6-5). An equivalent procedure in 'C' compiler language, using the MPLAB® C30 compiler and built-in hardware functions, is shown in Example 6-6.

EXAMPLE 6-5: PROGRAMMING A SINGLE WORD OF FLASH PROGRAM MEMORY

```
; Setup a pointer to data Program Memory
    MOV     #tblpage(PROG_ADDR), W0       ;
    MOV     W0, TBLPAG                    ;Initialize PM Page Boundary SFR
    MOV     #tbloffset(PROG_ADDR), W0     ;Initialize a register with program memory address

    MOV     #LOW_WORD_N, W2               ;
    MOV     #HIGH_BYTE_N, W3              ;
    TBLWTL  W2, [W0]                      ; Write PM low word into program latch
    TBLWTH  W3, [W0++]                    ; Write PM high byte into program latch

; Setup NVMCON for programming one word to data Program Memory
    MOV     #0x4003, W0                   ;
    MOV     W0, NVMCON                    ; Set NVMOP bits to 0011

    DISI    #5                            ; Disable interrupts while the KEY sequence is written
    MOV.B   #0x55, W0                     ; Write the key sequence
    MOV     W0, NVMKEY
    MOV.B   #0xAA, W0
    MOV     W0, NVMKEY
    BSET    NVMCON, #WR                   ; Start the write cycle
    NOP                                   ; Required delays
    NOP
```

EXAMPLE 6-6: PROGRAMMING A SINGLE WORD OF FLASH PROGRAM MEMORY ('C' LANGUAGE CODE)

```
// C example using MPLAB C30
unsigned int offset;
unsigned long progAddr = 0xXXXXXX;            // Address of word to program
unsigned int progDataL = 0xXXXX;              // Data to program lower word
unsigned char progDataH = 0xXX;               // Data to program upper byte

//Set up NVMCON for word programming
NVMCON = 0x4003;                              // Initialize NVMCON

//Set up pointer to the first memory location to be written
TBLPAG = progAddr>>16;                        // Initialize PM Page Boundary SFR
offset = progAddr & 0xFFFF;                   // Initialize lower word of address

//Perform TBLWT instructions to write latches
__builtin_tblwtl(offset, progDataL);          // Write to address low word
__builtin_tblwth(offset, progDataH);          // Write to upper byte
asm("DISI #5");                               // Block interrupts with priority <7
                                              // for next 5 instructions
__builtin_write_NVM();                        // C30 function to perform unlock
                                              // sequence and set WR
```

8.4 Interrupt Setup Procedures

8.4.1 INITIALIZATION

To configure an interrupt source:

1. Set the NSTDIS (INTCON1<15>) control bit if nested interrupts are not desired.
2. Select the user-assigned priority level for the interrupt source by writing the control bits in the appropriate IPCx register. The priority level will depend on the specific application and type of interrupt source. If multiple priority levels are not desired, the IPCx register control bits for all enabled interrupt sources may be programmed to the same non-zero value.

Note: At a device Reset, the IPCx registers are initialized, such that all user interrupt sources are assigned to Priority Level 4.

3. Clear the interrupt flag status bit associated with the peripheral in the associated IFSx register.
4. Enable the interrupt source by setting the interrupt enable control bit associated with the source in the appropriate IECx register.

8.4.2 INTERRUPT SERVICE ROUTINE (ISR)

The method that is used to declare an Interrupt Service Routine (ISR) and initialize the IVT with the correct vector address will depend on the programming language (i.e., 'C' or assembler) and the language development toolsuite that is used to develop the application. In general, the user must clear the interrupt flag in the appropriate IFSx register for the source of the interrupt that the ISR handles; otherwise, the ISR will be re-entered immediately after exiting the routine. If the ISR is coded in assembly language, it must be terminated using a `RETFIE` instruction to unstack the saved PC value, SRL value and old CPU priority level.

8.4.3 TRAP SERVICE ROUTINE (TSR)

A Trap Service Routine (TSR) is coded like an ISR, except that the appropriate trap status flag in the INTCON1 register must be cleared to avoid re-entry into the TSR.

8.4.4 INTERRUPT DISABLE

All user interrupts can be disabled using the following procedure:

1. Push the current SR value onto the software stack using the `PUSH` instruction.
2. Force the CPU to Priority Level 7 by inclusive ORing the value, 0Eh, with SRL.

To enable user interrupts, the `POP` instruction may be used to restore the previous SR value.

Note that only user interrupts with a priority level of 7 or less can be disabled. Trap sources (Levels 8-15) cannot be disabled.

The `DISI` instruction provides a convenient way to disable interrupts of Priority Levels 1-6 for a fixed period of time. Level 7 interrupt sources are not disabled by the `DISI` instruction.

NOTES:

© 2013-2015 Microchip Technology Inc.

11.1.1 I/O PORT WRITE/READ TIMING

One instruction cycle is required between a port direction change or port write operation and a read operation of the same port. Typically, this instruction would be a NOP.

11.1.2 OPEN-DRAIN CONFIGURATION

In addition to the PORTx, LATx and TRISx registers for data control, each port pin can also be individually configured for either a digital or open-drain output. This is controlled by the Open-Drain Control register, ODCx, associated with each port. Setting any of the bits configures the corresponding pin to act as an open-drain output.

The open-drain feature allows the generation of outputs higher than VDD (e.g., 5V), on any desired digital only pins, by using external pull-up resistors. The maximum open-drain voltage allowed is the same as the maximum VIH specification.

11.2 Configuring Analog Port Pins (ANSx)

The ANSx and TRISx registers control the operation of the pins with analog function. Each port pin with analog function is associated with one of the ANSx bits (see Register 11-1 through Register 11-3), which decides if the pin function should be analog or digital. Refer to Table 11-1 for detailed behavior of the pin for different ANSx and TRISx bit settings.

When reading the PORTx register, all pins configured as analog input channels will read as cleared (a low level).

11.2.1 ANALOG INPUT PINS AND VOLTAGE CONSIDERATIONS

The voltage tolerance of pins used as device inputs is dependent on the pin's input function. Most input pins are able to handle DC voltages of up to 5.5V, a level typical for digital logic circuits. However, several pins can only tolerate voltages up to VDD. Voltage excursions beyond VDD on these pins should always be avoided.

Table 11-2 summarizes the different voltage tolerances. For more information, refer to **Section 33.0 "Electrical Characteristics"** for more details.

TABLE 11-1: CONFIGURING ANALOG/DIGITAL FUNCTION OF AN I/O PIN

Pin Function	ANSx Setting	TRISx Setting	Comments
Analog Input	1	1	It is recommended to keep ANSx = 1.
Analog Output	1	1	It is recommended to keep ANSx = 1.
Digital Input	0	1	Firmware must wait at least one instruction cycle after configuring a pin as a digital input before a valid input value can be read.
Digital Output	0	0	Make sure to disable the analog output function on the pin if any is present.

TABLE 11-2: INPUT VOLTAGE LEVELS FOR PORT OR PIN TOLERATED DESCRIPTION INPUT

Port or Pin	Tolerated Input	Description
PORTA<10:7,4>(1)	5.5V	Tolerates input levels above VDD; useful for most standard logic.
PORTB<11:10,8:4>		
PORTC<9:3>(1)		
PORTA<3:0>	VDD	Only VDD input levels are tolerated.
PORTB<15:13,9,3:0>		
PORTC<2:0>(1)		

Note 1: Not all of these pins are implemented in 28-pin devices. Refer to **Section 1.0 "Device Overview"** for a complete description of port pin implementation.

11.4 Peripheral Pin Select (PPS)

A major challenge in general purpose devices is providing the largest possible set of peripheral features while minimizing the conflict of features on I/O pins. In an application that needs to use more than one peripheral multiplexed on a single pin, inconvenient work arounds in application code, or a complete redesign, may be the only option.

The Peripheral Pin Select (PPS) feature provides an alternative to these choices by enabling the user's peripheral set selection and its placement on a wide range of I/O pins. By increasing the pinout options available on a particular device, users can better tailor the microcontroller to their entire application, rather than trimming the application to fit the device.

The Peripheral Pin Select feature operates over a fixed subset of digital I/O pins. Users may independently map the input and/or output of any one of many digital peripherals to any one of these I/O pins. PPS is performed in software and generally does not require the device to be reprogrammed. Hardware safeguards are included that prevent accidental or spurious changes to the peripheral mapping once it has been established.

11.4.1 AVAILABLE PINS

The PPS feature is used with a range of up to 44 pins, depending on the particular device and its pin count. Pins that support the Peripheral Pin Select feature include the designation, "RPn" or "RPIn", in their full pin designation, where "n" is the remappable pin number. "RP" is used to designate pins that support both remappable input and output functions, while "RPI" indicates pins that support remappable input functions only.

PIC24FJ128GB204 family devices support a larger number of remappable input only pins than remappable input/output pins. In this device family, there are up to 25 remappable input/output pins, depending on the pin count of the particular device selected. These pins are numbered, RP0 through RP25.

See Table 1-3 for a summary of pinout options in each package offering.

11.4.2 AVAILABLE PERIPHERALS

The peripherals managed by the PPS are all digital only peripherals. These include general serial communications (UART and SPI), general purpose timer clock inputs, timer related peripherals (input capture and output compare) and external interrupt inputs. Also included are the outputs of the comparator module, since these are discrete digital signals.

PPS is not available for these peripherals:

- I^2C™ (input and output)
- USB (all module inputs and outputs)
- Change Notification Inputs
- RTCC Alarm Output(s)
- EPMP Signals (input and output)
- Analog (inputs and outputs)
- INT0

A key difference between pin select and non-pin select peripherals is that pin select peripherals are not associated with a default I/O pin. The peripheral must always be assigned to a specific I/O pin before it can be used. In contrast, non-pin select peripherals are always available on a default pin, assuming that the peripheral is active and not conflicting with another peripheral.

11.4.2.1 Peripheral Pin Select Function Priority

Pin-selectable peripheral outputs (e.g., OC, UART transmit) will take priority over general purpose digital functions on a pin, such as EPMP and port I/O. Specialized digital outputs (e.g., USB on USB-enabled devices) will take priority over PPS outputs on the same pin. The pin diagrams list peripheral outputs in the order of priority. Refer to them for priority concerns on a particular pin.

Unlike PIC24F devices with fixed peripherals, pin-selectable peripheral inputs will never take ownership of a pin. The pin's output buffer will be controlled by the TRISx setting or by a fixed peripheral on the pin. If the pin is configured in Digital mode, then the PPS input will operate correctly. If an analog function is enabled on the pin, the PPS input will be disabled.

11.4.3 CONTROLLING PERIPHERAL PIN SELECT

PPS features are controlled through two sets of Special Function Registers (SFRs): one to map peripheral inputs and one to map outputs. Because they are separately controlled, a particular peripheral's input and output (if the peripheral has both) can be placed on any selectable function pin without constraint.

The association of a peripheral to a peripheral-selectable pin is handled in two different ways, depending on if an input or an output is being mapped.

© 2013-2015 Microchip Technology Inc.

11.4.3.2 Output Mapping

In contrast to inputs, the outputs of the Peripheral Pin Select options are mapped on the basis of the pin. In this case, a control register associated with a particular pin dictates the peripheral output to be mapped. The RPORx registers are used to control output mapping. Each register contains two 6-bit fields, with each field being associated with one RPn pin (see Register 11-23 through Register 11-35). The value of the bit field corresponds to one of the peripherals and that peripheral's output is mapped to the pin (see Table 11-4).

Because of the mapping technique, the list of peripherals for output mapping also includes a null value of '000000'. This permits any given pin to remain disconnected from the output of any of the pin-selectable peripherals.

TABLE 11-4: SELECTABLE OUTPUT SOURCES (MAPS FUNCTION TO OUTPUT)

Output Function Number(1)	Function	Output Name
0	NULL(2)	Null
1	C1OUT	Comparator 1 Output
2	C2OUT	Comparator 2 Output
3	U1TX	UART1 Transmit
4	$\overline{\text{U1RTS}}$(3)	UART1 Request-to-Send
5	U2TX	UART2 Transmit
6	$\overline{\text{U2RTS}}$(3)	UART2 Request-to-Send
7	SDO1	SPI1 Data Output
8	SCK1OUT	SPI1 Clock Output
9	SS1OUT	SPI1 Slave Select Output
10	SDO2	SPI2 Data Output
11	SCK2OUT	SPI2 Clock Output
12	SS2OUT	SPI2 Slave Select Output
13	OC1	Output Compare 1
14	OC2	Output Compare 2
15	OC3	Output Compare 3
16	OC4	Output Compare 4
17	OC5	Output Compare 5
18	OC6	Output Compare 6
19	U3TX	UART3 Transmit
20	$\overline{\text{U3RTS}}$	UART3 Request-to-Send
21	U4TX	UART4 Transmit
22	$\overline{\text{U4RTS}}$(3)	UART4 Request-to-Send
23	SDO3	SPI3 Data Output
24	SCK3OUT	SPI3 Clock Output
25	SS3OUT	SPI3 Slave Select Output
26	C3OUT	Comparator 3 Output
27	MDOUT	DSM Modulator Output

Note 1: Setting the RPORx register with the listed value assigns that output function to the associated RPn pin.

2: The NULL function is assigned to all RPn outputs at device Reset and disables the RPn output function.

3: IrDA® BCLK functionality uses this output.

30.0 SPECIAL FEATURES

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the following sections of the *"dsPIC33/PIC24 Family Reference Manual"*. The information in this data sheet supersedes the information in the FRMs.

- **"Watchdog Timer (WDT)"** (DS39697)
- **"High-Level Device Integration"** (DS39719)
- **"Programming and Diagnostics"** (DS39716)

PIC24FJ128GB204 family devices include several features intended to maximize application flexibility and reliability, and minimize cost through elimination of external components. These are:

- Flexible Configuration
- Watchdog Timer (WDT)
- Code Protection
- JTAG Boundary Scan Interface
- In-Circuit Serial Programming™ (ICSP™)
- In-Circuit Emulation (ICE)

30.1 Configuration Bits

The Configuration bits can be programmed (read as '0'), or left unprogrammed (read as '1'), to select various device configurations. These bits are mapped starting at program memory location, F80000h. A detailed explanation of the various bit functions is provided in Register 30-1 through Register 30-6.

Note that address, F80000h, is beyond the user program memory space. In fact, it belongs to the configuration memory space (800000h-FFFFFFh), which can only be accessed using Table Reads and Table Writes.

30.1.1 CONSIDERATIONS FOR CONFIGURING PIC24FJ128GB204 FAMILY DEVICES

In PIC24FJ128GB204 family devices, the Configuration bytes are implemented as volatile memory. This means that configuration data must be programmed each time the device is powered up. Configuration data is stored in the four words at the top of the on-chip program memory space, known as the Flash Configuration Words. Their specific locations are shown in Table 30-1. These are packed representations of the actual device Configuration bits, whose actual locations are distributed among several locations in configuration space. The configuration data is automatically loaded from the Flash Configuration Words to the proper Configuration registers during device Resets.

Note: Configuration data is reloaded on all types of device Resets.

When creating applications for these devices, users should always specifically allocate the location of the Flash Configuration Word for configuration data. This is to make certain that program code is not stored in this address when the code is compiled.

The upper byte of all Flash Configuration Words in program memory should always be: '0000 0000'. This makes them appear to be NOP instructions in the remote event that their locations are ever executed by accident. Since Configuration bits are not implemented in the corresponding locations, writing '0's to these locations has no effect on device operation.

Note: Performing a page erase operation on the last page of program memory clears the Flash Configuration Words, enabling code protection as a result. Therefore, users should avoid performing page erase operations on the last page of program memory.

TABLE 30-1: FLASH CONFIGURATION WORD LOCATIONS FOR THE PIC24FJ128GB204 FAMILY

Device	Configuration Word Addresses			
	1	2	3	4
PIC24FJ64GB2XX	ABFEh	ABFCh	ABFAh	ABF8h
