Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Logic Module Design

The SX-A family architecture is described as a “sea-of-modules” architecture because the entire floor of the device is covered with a grid of logic modules with virtually no chip area lost to interconnect elements or routing. The Actel SX-A family provides two types of logic modules: the register cell (R-cell) and the combinatorial cell (C-cell).

The R-cell contains a flip-flop featuring asynchronous clear, asynchronous preset, and clock enable, using the S0 and S1 lines control signals (Figure 1-2). The R-cell registers feature programmable clock polarity selectable on a register-by-register basis. This provides additional flexibility while allowing mapping of synthesized functions into the SX-A FPGA. The clock source for the R-cell can be chosen from either the hardwired clock, the routed clocks, or internal logic.

The C-cell implements a range of combinatorial functions of up to five inputs (Figure 1-3). Inclusion of the DB input and its associated inverter function allows up to 4,000

different combinatorial functions to be implemented in a single module. An example of the flexibility enabled by the inversion capability is the ability to integrate a 3-input exclusive-OR function into a single C-cell. This facilitates construction of 9-bit parity-tree functions with 1.9 ns propagation delays.

Module Organization

All C-cell and R-cell logic modules are arranged into horizontal banks called Clusters. There are two types of Clusters: Type 1 contains two C-cells and one R-cell, while Type 2 contains one C-cell and two R-cells.

Clusters are grouped together into SuperClusters (Figure 1-4 on page 1-3). SuperCluster 1 is a two-wide grouping of Type 1 Clusters. SuperCluster 2 is a two-wide group containing one Type 1 Cluster and one Type 2 Cluster. SX-A devices feature more SuperCluster 1 modules than SuperCluster 2 modules because designers typically require significantly more combinatorial logic than flip-flops.

Other Architectural Features

Technology

The Actel SX-A family is implemented on a high-voltage, twin-well CMOS process using $0.22\ \mu\text{m}$ / $0.25\ \mu\text{m}$ design rules. The metal-to-metal antifuse is comprised of a combination of amorphous silicon and dielectric material with barrier metals and has a programmed ('on' state) resistance of $25\ \Omega$ with capacitance of $1.0\ \text{fF}$ for low signal impedance.

Performance

The unique architectural features of the SX-A family enable the devices to operate with internal clock frequencies of 350 MHz, causing very fast execution of even complex logic functions. The SX-A family is an optimal platform upon which to integrate the functionality previously contained in multiple complex programmable logic devices (CPLDs). In addition, designs that previously would have required a gate array to meet performance goals can be integrated into an SX-A device with dramatic improvements in cost and time-to-market. Using timing-driven place-and-route tools, designers can achieve highly deterministic device performance.

User Security

Reverse engineering is virtually impossible in SX-A devices because it is extremely difficult to distinguish between programmed and unprogrammed antifuses. In addition, since SX-A is a nonvolatile, single-chip solution, there is no configuration bitstream to intercept at device power-up.

The Actel FuseLock advantage ensures that unauthorized users will not be able to read back the contents of an Actel antifuse FPGA. In addition to the inherent strengths of the architecture, special security fuses that prevent internal probing and overwriting are hidden throughout the fabric of the device. They are located where they cannot be accessed or bypassed without destroying access to the rest of the device, making both invasive and more-subtle noninvasive attacks ineffective against Actel antifuse FPGAs.

Look for this symbol to ensure your valuable IP is secure (Figure 1-11).

I/O Modules

For a simplified I/O schematic, refer to Figure 1 in the application note, *Actel eX, SX-A, and RTSX-S I/Os*.

Each user I/O on an SX-A device can be configured as an input, an output, a tristate output, or a bidirectional pin. Mixed I/O standards can be set for individual pins, though this is only allowed with the same voltage as the input. These I/Os, combined with array registers, can achieve clock-to-output-pad timing as fast as 3.8 ns, even without the dedicated I/O registers. In most FPGAs, I/O cells that have embedded latches and flip-flops, requiring instantiation in HDL code; this is a design complication not encountered in SX-A FPGAs. Fast pin-to-pin timing ensures that the device is able to interface with any other device in the system, which in turn enables parallel design of system components and reduces overall design time. All unused I/Os are configured as tristate outputs by the Actel Designer software, for maximum flexibility when designing new boards or migrating existing designs.

SX-A I/Os should be driven by high-speed push-pull devices with a low-resistance pull-up device when being configured as tristate output buffers. If the I/O is driven by a voltage level greater than V_{CC1} and a fast push-pull device is NOT used, the high-resistance pull-up of the driver and the internal circuitry of the SX-A I/O may create a voltage divider. This voltage divider could pull the input voltage below specification for some devices connected to the driver. A logic '1' may not be correctly presented in this case. For example, if an open drain driver is used with a pull-up resistor to 5 V to provide the logic '1' input, and V_{CC1} is set to 3.3 V on the SX-A device, the input signal may be pulled down by the SX-A input.

Each I/O module has an available power-up resistor of approximately $50\ \text{k}\Omega$ that can configure the I/O in a known state during power-up. For nominal pull-up and pull-down resistor values, refer to Table 1-4 on page 1-8 of the application note *Actel eX, SX-A, and RTSX-S I/Os*. Just slightly before V_{CCA} reaches 2.5 V, the resistors are disabled, so the I/Os will be controlled by user logic. See Table 1-2 on page 1-8 and Table 1-3 on page 1-8 for more information concerning available I/O features.

Notes:

1. Refer to the *VII* curves in Figure 2-1 on page 2-5. Switching current characteristics for REQ# and GNT# are permitted to be one half of that specified here; i.e., half size output drivers may be used on these signals. This specification does not apply to CLK and RST#, which are system outputs. "Switching Current High" specifications are not relevant to SERR#, INTA#, INTB#, INTC#, and INTD#, which are open drain outputs.
2. Note that this segment of the minimum current curve is drawn from the AC drive point directly to the DC drive point rather than toward the voltage rail (as is done in the pull-down curve). This difference is intended to allow for an optional N-channel pull-up.
3. Maximum current requirements must be met as drivers pull beyond the last step voltage. Equations defining these maximums (A and B) are provided with the respective diagrams in Figure 2-1 on page 2-5. The equation defined maximum should be met by design. In order to facilitate component testing, a maximum current test point is defined for each side of the output driver.
4. This parameter is to be interpreted as the cumulative edge rate across the specified range, rather than the instantaneous rate at any point within the transition range. The specified load (diagram below) is optional; i.e., the designer may elect to meet this parameter with an unloaded output per revision 2.0 of the PCI Local Bus Specification. However, adherence to both maximum and minimum parameters is now required (the maximum is no longer simply a guideline). Since adherence to the maximum slew rate was not required prior to revision 2.1 of the specification, there may be components in the market for some time that have faster edge rates; therefore, motherboard designers must bear in mind that rise and fall times faster than this specification could occur and should ensure that signal integrity modeling accounts for this. Rise slew rate does not apply to open drain outputs.

Power Dissipation

A critical element of system reliability is the ability of electronic devices to safely dissipate the heat generated during operation. The thermal characteristics of a circuit depend on the device and package used, the operating temperature, the operating current, and the system's ability to dissipate heat.

A complete power evaluation should be performed early in the design process to help identify potential heat-related problems in the system and to prevent the system from exceeding the device's maximum allowed junction temperature.

The actual power dissipated by most applications is significantly lower than the power the package can dissipate. However, a thermal analysis should be performed for all projects. To perform a power evaluation, follow these steps:

1. Estimate the power consumption of the application.
2. Calculate the maximum power allowed for the device and package.
3. Compare the estimated power and maximum power values.

Estimating Power Dissipation

The total power dissipation for the SX-A family is the sum of the DC power dissipation and the AC power dissipation:

$$P_{\text{Total}} = P_{\text{DC}} + P_{\text{AC}}$$

EQ 2-5

DC Power Dissipation

The power due to standby current is typically a small component of the overall power. An estimation of DC power dissipation under typical conditions is given by:

$$P_{\text{DC}} = I_{\text{standby}} * V_{\text{CCA}}$$

EQ 2-6

Note: For other combinations of temperature and voltage settings, refer to the *eX, SX-A and RT54SX-S Power Calculator*.

AC Power Dissipation

The power dissipation of the SX-A family is usually dominated by the dynamic power dissipation. Dynamic power dissipation is a function of frequency, equivalent capacitance, and power supply voltage. The AC power dissipation is defined as follows:

$$P_{\text{AC}} = P_{\text{C-cells}} + P_{\text{R-cells}} + P_{\text{CLKA}} + P_{\text{CLKB}} + P_{\text{HCLK}} + P_{\text{Output Buffer}} + P_{\text{Input Buffer}}$$

EQ 2-7

or:

$$P_{\text{AC}} = V_{\text{CCA}}^2 * [(m * C_{\text{EQCM}} * f_m)_{\text{C-cells}} + (m * C_{\text{EQSM}} * f_m)_{\text{R-cells}} + (n * C_{\text{EQI}} * f_n)_{\text{Input Buffer}} + (p * (C_{\text{EQO}} + C_L) * f_p)_{\text{Output Buffer}} + (0.5 * (q_1 * C_{\text{EQCR}} * f_{q1}) + (r_1 * f_{q1}))_{\text{CLKA}} + (0.5 * (q_2 * C_{\text{EQCR}} * f_{q2}) + (r_2 * f_{q2}))_{\text{CLKB}} + (0.5 * (s_1 * C_{\text{EQHV}} * f_{s1}) + (C_{\text{EQHF}} * f_{s1}))_{\text{HCLK}]$$

Notes:

1. All -3 speed grades have been discontinued.
2. For dual-module macros, use $t_{PD} + t_{RD1} + t_{PDn}$, $t_{RCO} + t_{RD1} + t_{PDn}$, or $t_{PD1} + t_{RD1} + t_{SUD}$, whichever is appropriate.
3. Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual performance.
