### **Understanding Embedded - FPGAs (Field Programmable Gate Array)**

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

### **Applications of Embedded - FPGAs**

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

## Power Dissipation

A critical element of system reliability is the ability of electronic devices to safely dissipate the heat generated during operation. The thermal characteristics of a circuit depend on the device and package used, the operating temperature, the operating current, and the system's ability to dissipate heat.

A complete power evaluation should be performed early in the design process to help identify potential heat-related problems in the system and to prevent the system from exceeding the device's maximum allowed junction temperature.

The actual power dissipated by most applications is significantly lower than the power the package can dissipate. However, a thermal analysis should be performed for all projects. To perform a power evaluation, follow these steps:

1. Estimate the power consumption of the application.
2. Calculate the maximum power allowed for the device and package.
3. Compare the estimated power and maximum power values.

### Estimating Power Dissipation

The total power dissipation for the SX-A family is the sum of the DC power dissipation and the AC power dissipation:

$$P_{\text{Total}} = P_{\text{DC}} + P_{\text{AC}}$$

*EQ 2-5*

### DC Power Dissipation

The power due to standby current is typically a small component of the overall power. An estimation of DC power dissipation under typical conditions is given by:

$$P_{\text{DC}} = I_{\text{Standby}} * V_{\text{CCA}}$$

*EQ 2-6*

Note: For other combinations of temperature and voltage settings, refer to the *eX, SX-A and RT54SX-S Power Calculator*.

### AC Power Dissipation

The power dissipation of the SX-A family is usually dominated by the dynamic power dissipation. Dynamic power dissipation is a function of frequency, equivalent capacitance, and power supply voltage. The AC power dissipation is defined as follows:

$$P_{\text{AC}} = P_{\text{C-cells}} + P_{\text{R-cells}} + P_{\text{CLKA}} + P_{\text{CLKB}} + P_{\text{HCLK}} + P_{\text{Output Buffer}} + P_{\text{Input Buffer}}$$

*EQ 2-7*

or:

$$\begin{aligned} P_{\text{AC}} = & V_{\text{CCA}}^2 * [(m * C_{\text{EQCM}} * f_m)_{\text{C-cells}} + (m * C_{\text{EQSM}} * f_m)_{\text{R-cells}} + (n * C_{\text{EQI}} * f_n)_{\text{Input Buffer}} + (p * (C_{\text{EQO}} + C_L) * f_p)_{\text{Output Buffer}} \\ & + (0.5 * (q_1 * C_{\text{EQCR}} * f_{q1}) + (r_1 * f_{q1}))_{\text{CLKA}} + (0.5 * (q_2 * C_{\text{EQCR}} * f_{q2}) + (r_2 * f_{q2}))_{\text{CLKB}} + (0.5 * (s_1 * C_{\text{EQHV}} * f_{s1}) + \\ & (C_{\text{EQHF}} * f_{s1}))_{\text{HCLK}}] \end{aligned}$$

*EQ 2-8*

## Theta-JA

Junction-to-ambient thermal resistance ( $\theta_{JA}$ ) is determined under standard conditions specified by JESD-51 series but has little relevance in actual performance of the product in real application. It should be employed with caution but is useful for comparing the thermal performance of one package to another.

A sample calculation to estimate the absolute maximum power dissipation allowed (worst case) for a 329-pin PBGA package at still air is as follows. i.e.:

$\theta_{JA} = 17.1^\circ\text{C/W}$  is taken from Table 2-12 on page 2-11

$T_A = 125^\circ\text{C}$  is the maximum limit of ambient (from the datasheet)

$$\text{Max. Allowed Power} = \frac{\text{Max Junction Temp} - \text{Max. Ambient Temp}}{\theta_{JA}} = \frac{150^\circ\text{C} - 125^\circ\text{C}}{17.1^\circ\text{C/W}} = 1.46 \text{ W}$$

EQ 2-11

The device's power consumption must be lower than the calculated maximum power dissipation by the package.

The power consumption of a device can be calculated using the Actel power calculator. If the power consumption is higher than the device's maximum allowable power dissipation, then a heat sink can be attached on top of the case or the airflow inside the system must be increased.

## Theta-JC

Junction-to-case thermal resistance ( $\theta_{JC}$ ) measures the ability of a device to dissipate heat from the surface of the chip to the top or bottom surface of the package. It is applicable for packages used with external heat sinks and only applies to situations where all or nearly all of the heat is dissipated through the surface in consideration. If the power consumption is higher than the calculated maximum power dissipation of the package, then a heat sink is required.

## Calculation for Heat Sink

For example, in a design implemented in a FG484 package, the power consumption value using the power calculator is 3.00 W. The user-dependent data  $T_J$  and  $T_A$  are given as follows:

$T_J = 110^\circ\text{C}$

$T_A = 70^\circ\text{C}$

From the datasheet:

$\theta_{JA} = 18.0^\circ\text{C/W}$

$\theta_{JC} = 3.2^\circ\text{C/W}$

$$P = \frac{\text{Max Junction Temp} - \text{Max. Ambient Temp}}{\theta_{JA}} = \frac{110^\circ\text{C} - 70^\circ\text{C}}{18.0^\circ\text{C/W}} = 2.22 \text{ W}$$

EQ 2-12

The 2.22 W power is less than then required 3.00 W; therefore, the design requires a heat sink or the airflow where the device is mounted should be increased. The design's junction-to-air thermal resistance requirement can be estimated by:

$$\theta_{JA} = \frac{\text{Max Junction Temp} - \text{Max. Ambient Temp}}{P} = \frac{110^\circ\text{C} - 70^\circ\text{C}}{3.00 \text{ W}} = 13.33^\circ\text{C/W}$$

EQ 2-13

**Notes:**

1. All -3 speed grades have been discontinued.
2. Delays based on 50 pF loading.
3. To obtain the slew rate, substitute the appropriate Delta value, load capacitance, and the  $V_{CCI}$  value into the following equation:  

$$\text{Slew Rate [V/ns]} = (0.1 * V_{CCI} - 0.9 * V_{CCI}) / (C_{load} * d_{T[LH|HL|HLS]})$$

where  $C_{load}$  is the load capacitance driven by the I/O in pF

$d_{T[LH|HL|HLS]}$  is the worst case delta value from the datasheet in ns/pF.
4. Delays based on 35 pF loading.
