What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

		48 KB EEPROM backup	—	—	—	—		
		64 KB EEPROM backup	—	—	—	—		
$t_{quickwr}$	32-bit Quick Write execution time: Time from CCIF clearing (start the write) until CCIF setting (32-bit write complete, ready for next 32-bit write)	1st 32-bit write	200	550	200	550	µs	4,5,6
		2nd through Next to Last (Nth-1) 32-bit write	150	550	150	550		
		Last (Nth) 32-bit write (time for write only, not cleanup)	200	550	200	550		
$t_{quickwrClnup}$	Quick Write Cleanup execution time	—	—	(# of Quick Writes) * 2.0	—	(# of Quick Writes) * 2.0	ms	7

1. All command times assume 25 MHz or greater flash clock frequency (for synchronization time between internal/external clocks).
2. Maximum times for erase parameters based on expectations at cycling end-of-life.
3. For all EEPROM Emulation terms, the specified timing shown assumes previous record cleanup has occurred. This may be verified by executing FCCOB Command 0x77, and checking FCCOB number 5 contents show 0x00 - No EEPROM issues detected.
4. 1st time EERAM writes after a Reset or SETRAM may incur additional overhead for EEE cleanup, resulting in up to 2x the times shown.
5. Only after the Nth write completes will any data be valid. Emulated EEPROM record scheme cleanup overhead may occur after this point even after a brownout or reset. If power on reset occurs before the Nth write completes, the last valid record set will still be valid and the new records will be discarded.
6. Quick Write times may take up to 550 µs, as additional cleanup may occur when crossing sector boundaries.
7. Time for emulated EEPROM record scheme overhead cleanup. Automatically done after last (Nth) write completes, assuming still powered. Or via SETRAM cleanup execution command is requested at a later point.

NOTE

Under certain circumstances FlexMEM maximum times may be exceeded. In this case the user or application may wait, or assert reset to the FTFC macro to stop the operation.

Table 27. 12-bit ADC operating conditions (continued)

Symbol	Description	Conditions	Min.	Typ.[1]	Max.	Unit	Notes
f_{ADCK}	ADC conversion clock frequency	Normal usage	2	40	50	MHz	3, 4
f_{CONV}	ADC conversion frequency	No ADC hardware averaging.[5] Continuous conversions enabled, subsequent conversion time	46.4	928	1160	Ksps	6, 7
		ADC hardware averaging set to 32. [5] Continuous conversions enabled, subsequent conversion time	1.45	29	36.25	Ksps	6, 7

1. Typical values assume V_{DDA} = 5 V, Temp = 25 °C, f_{ADCK} = 40 MHz, R_{AS}=20 Ω, and C_{AS}=10 nF unless otherwise stated. Typical values are for reference only, and are not tested in production.
2. For packages without dedicated V_{REFH} and V_{REFL} pins, V_{REFH} is internally tied to V_{DDA}, and V_{REFL} is internally tied to V_{SS}. To get maximum performance, reference supply quality should be better than SAR ADC. See application note AN5032 for details.
3. Clock and compare cycle need to be set according to the guidelines mentioned in the *Reference Manual* .
4. ADC conversion will become less reliable above maximum frequency.
5. When using ADC hardware averaging, see the *Reference Manual* to determine the most appropriate setting for AVGS.
6. Numbers based on the minimum sampling time of 275 ns.
7. For guidelines and examples of conversion rate calculation, see the *Reference Manual* section 'Calibration function'
