What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

4. When input pad voltage levels are close to V_{DD} or V_{SS}, practically no current injection is possible.
5. While respecting the maximum current injection limit
6. This is the Electronic Control Unit (ECU) supply ramp rate and not directly the MCU ramp rate. Limit applies to both maximum absolute maximum ramp rate and typical operating conditions.
7. This is the MCU supply ramp rate and the ramp rate assumes that the S32K1xx HW design guidelines in AN5426 are followed. Limit applies to both maximum absolute maximum ramp rate and typical operating conditions.
8. T_J (Junction temperature)=135 °C. Assumes T_A=125 °C for RUN mode

   T_J (Junction temperature)=125 °C. Assumes TA=105 °C for HSRUN mode

4.2 Voltage and current operating requirements

NOTE

Device functionality is guaranteed up to the LVR assert level, however electrical performance of 12-bit ADC, CMP with 8-bit DAC, IO electrical characteristics, and communication modules electrical characteristics would be degraded when voltage drops below 2.7 V

Table 2. Voltage and current operating requirements 1

Symbol	Description	Min.	Max.	Unit	Notes
V_{DD}[2]	Supply voltage	2.7[3]	5.5	V	4
V_{DD_OFF}	Voltage allowed to be developed on V_{DD} pin when it is not powered from any external power supply source.	0	0.1	V	
V_{DDA}	Analog supply voltage	2.7	5.5	V	4
$V_{DD} – V_{DDA}$	V_{DD}-to-V_{DDA} differential voltage	– 0.1	0.1	V	4
V_{REFH}	ADC reference voltage high	2.7	V_{DDA} + 0.1	V	5
V_{REFL}	ADC reference voltage low	-0.1	0.1	V	
V_{ODPU}	Open drain pullup voltage level	V_{DD}	V_{DD}	V	6
$I_{INJPAD\_DC\_OP}$[7]	Continuous DC input current (positive / negative) that can be injected into an I/O pin	-3	+3	mA	
$I_{INJSUM\_DC\_OP}$	Continuous total DC input current that can be injected across all I/O pins such that there's no degradation in accuracy of analog modules: ADC and ACMP (See section Analog Modules)	—	30	mA	

1. Typical conditions assumes V_{DD} = V_{DDA} = V_{REFH} = 5 V, temperature = 25 °C and typical silicon process unless otherwise stated.
2. As V_{DD} varies between the minimum value and the absolute maximum value the analog characteristics of the I/O and the ADC will both change. See section I/O parameters and ADC electrical specifications respectively for details.
3. S32K148 will operate from 2.7 V when executing from internal FIRC. When the PLL is engaged S32K148 is guaranteed to operate from 2.97 V. All other S32K family devices operate from 2.7 V in all modes.
4. V_{DD} and V_{DDA} must be shorted to a common source on PCB. The differential voltage between V_{DD} and V_{DDA} is for RF-AC only. Appropriate decoupling capacitors to be used to filter noise on the supplies. See application note AN5032 for reference supply design for SAR ADC.

NOTE: V_{DD} and V_{DDA} must be shorted to a common source on PCB

7.3 General notes for specifications at maximum junction temperature

An estimation of the chip junction temperature, T_J, can be obtained from this equation:

$$T_J = T_A + (R_{\theta JA} \times P_D)$$

where:

- T_A = ambient temperature for the package (°C)
- $R_{\theta JA}$ = junction to ambient thermal resistance (°C/W)
- P_D = power dissipation in the package (W)

The junction to ambient thermal resistance is an industry standard value that provides a quick and easy estimation of thermal performance. Unfortunately, there are two values in common usage: the value determined on a single layer board and the value obtained on a board with two planes. For packages such as the PBGA, these values can be different by a factor of two. Which value is closer to the application depends on the power dissipated by other components on the board. The value obtained on a single layer board is appropriate for the tightly packed printed circuit board. The value obtained on the board with the internal planes is usually appropriate if the board has low power dissipation and the components are well separated.

When a heat sink is used, the thermal resistance is expressed in the following equation as the sum of a junction-to-case thermal resistance and a case-to-ambient thermal resistance:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CA}$$

where:

- $R_{\theta JA}$ = junction to ambient thermal resistance (°C/W)
- $R_{\theta JC}$ = junction to case thermal resistance (°C/W)
- $R_{\theta CA}$ = case to ambient thermal resistance (°C/W)

$R_{\theta JC}$ is device related and cannot be influenced by the user. The user controls the thermal environment to change the case to ambient thermal resistance, $R_{\theta CA}$. For instance, the user can change the size of the heat sink, the air flow around the device, the interface material, the mounting arrangement on printed circuit board, or change the thermal dissipation on the printed circuit board surrounding the device.
