### Understanding [Embedded - CPLDs \(Complex Programmable Logic Devices\)](#)

Embedded - CPLDs, or Complex Programmable Logic Devices, are highly versatile digital logic devices used in electronic systems. These programmable components are designed to perform complex logical operations and can be customized for specific applications. Unlike fixed-function ICs, CPLDs offer the flexibility to reprogram their configuration, making them an ideal choice for various embedded systems. They consist of a set of logic gates and programmable interconnects, allowing designers to implement complex logic circuits without needing custom hardware.

### Applications of Embedded - CPLDs

#### Details

|                                 |                                                                                                                                                                         |

**Architecture Overview of Ultra37000 Family**
**Programmable Interconnect Matrix**

The PIM consists of a completely global routing matrix for signals from I/O pins and feedbacks from the logic blocks. The PIM provides extremely robust interconnection to avoid fitting and density limitations.

The inputs to the PIM consist of all I/O and dedicated input pins and all macrocell feedbacks from within the logic blocks. The number of PIM inputs increases with pin count and the number of logic blocks. The outputs from the PIM are signals routed to the appropriate logic blocks. Each logic block receives 36 inputs from the PIM and their complements, allowing for 32-bit operations to be implemented in a single pass through the device. The wide number of inputs to the logic block also improves the routing capacity of the Ultra37000 family.

An important feature of the PIM is its simple timing. The propagation delay through the PIM is accounted for in the timing specifications for each device. There is no additional delay for traveling through the PIM. In fact, all inputs travel through the PIM. As a result, there are no route-dependent timing parameters on the Ultra37000 devices. The worst-case PIM delays are incorporated in all appropriate Ultra37000 specifications.

Routing signals through the PIM is completely invisible to the user. All routing is accomplished by software—no hand routing is necessary. *Warp*® and third-party development packages automatically route designs for the Ultra37000 family in a matter of minutes. Finally, the rich routing resources of the Ultra37000 family accommodate last minute logic changes while maintaining fixed pin assignments.

**Logic Block**

The logic block is the basic building block of the Ultra37000 architecture. It consists of a product term array, an intelligent product-term allocator, 16 macrocells, and a number of I/O cells. The number of I/O cells varies depending on the device used. Refer to *Figure 1* for the block diagram.

**Product Term Array**

Each logic block features a 72 x 87 programmable product term array. This array accepts 36 inputs from the PIM, which originate from macrocell feedbacks and device pins. Active LOW and active HIGH versions of each of these inputs are generated to create the full 72-input field. The 87 product terms in the array can be created from any of the 72 inputs.

Of the 87 product terms, 80 are for general-purpose use for the 16 macrocells in the logic block. Four of the remaining seven product terms in the logic block are output enable (OE) product terms. Each of the OE product terms controls up to eight of the 16 macrocells and is selectable on an individual macrocell basis. In other words, each I/O cell can select between one of two OE product terms to control the output buffer. The first two of these four OE product terms are available to the upper half of the I/O macrocells in a logic block. The other two OE product terms are available to the lower half of the I/O macrocells in a logic block.

The next two product terms in each logic block are dedicated asynchronous set and asynchronous reset product terms. The final product term is the product term clock. The set, reset, OE and product term clock have polarity control to realize OR functions in a single pass through the array.

**Figure 3. Input Macrocell**

**Figure 4. Input/Clock Macrocell**

### Clocking

Each I/O and buried macrocell has access to four synchronous clocks (CLK0, CLK1, CLK2 and CLK3) as well as an asynchronous product term clock PTCLK. Each input macrocell has access to all four synchronous clocks.

#### Dedicated Inputs/Clocks

Five pins on each member of the Ultra37000 family are designated as input-only. There are two types of dedicated inputs on Ultra37000 devices: input pins and input/clock pins. *Figure 3* illustrates the architecture for input pins. Four input options are available for the user: combinatorial, registered, double-registered, or latched. If a registered or latched option is selected, any one of the input clocks can be selected for control.

*Figure 4* illustrates the architecture for the input/clock pins. Like the input pins, input/clock pins can be combinatorial, registered, double-registered, or latched. In addition, these pins feed the clocking structures throughout the device. The clock path at the input has user-configurable polarity.

#### Product Term Clocking

In addition to the four synchronous clocks, the Ultra37000 family also has a product term clock for asynchronous clocking. Each logic block has an independent product term clock which is available to all 16 macrocells. Each product term clock also supports user configurable polarity selection.

### Timing Model

One of the most important features of the Ultra37000 family is the simplicity of its timing. All delays are worst case and system performance is unaffected by the features used. *Figure 5* illustrates the true timing model for the 167-MHz devices in high speed mode. For combinatorial paths, any input to any output incurs a 6.5-ns worst-case delay regardless of the amount of logic used. For synchronous systems, the input set-up time to the output macrocells for any input is 3.5 ns and the clock to output time is also 4.0 ns. These measurements are for any output and synchronous clock, regardless of the logic used.

The Ultra37000 features:

- No fanout delays
- No expander delays
- No dedicated vs. I/O pin delays
- No additional delay through PIM
- No penalty for using 0–16 product terms
- No added delay for steering product terms
- No added delay for sharing product terms
- No routing delays
- No output bypass delays

The simple timing model of the Ultra37000 family eliminates unexpected performance penalties.

## 5.0V Device Characteristics

### Maximum Ratings

(Above which the useful life may be impaired. For user guidelines, not tested.)

Storage Temperature ..... -65°C to +150°C

Ambient Temperature with

Power Applied ..... -55°C to +125°C

Supply Voltage to Ground Potential ..... -0.5V to +7.0V

DC Voltage Applied to Outputs

in High-Z State ..... -0.5V to +7.0V

DC Input Voltage ..... -0.5V to +7.0V

DC Program Voltage ..... 4.5 to 5.5V

Current into Outputs ..... 16 mA

Static Discharge Voltage ..... > 2001V  
(per MIL-STD-883, Method 3015)

Latch-up Current ..... > 200 mA

### Operating Range<sup>[2]</sup>

| Range                   | Ambient Temperature <sup>[2]</sup> | Junction Temperature | Output Condition | V <sub>CC</sub> | V <sub>CCO</sub> |

#### Notes:

- Normal Programming Conditions apply across Ambient Temperature Range for specified programming methods. For more information on programming the Ultra37000 Family devices, please refer to the Application Note titled "An Introduction to In System Reprogramming with the Ultra37000."
- T<sub>A</sub> is the "Instant On" case temperature.
- I<sub>OH</sub> = -2 mA, I<sub>OL</sub> = 2 mA for TDO.
- Tested initially and after any design or process changes that may affect these parameters.
- When the I/O is output disabled, the bus-hold circuit can weakly pull the I/O to above 3.6V if no leakage current is allowed. Note that all I/Os are output disabled during ISR programming. Refer to the application note "Understanding Bus-Hold" for additional information.
- These are absolute values with respect to device ground. All overshoots due to system or tester noise are included.
- Not more than one output should be tested at a time. Duration of the short circuit should not exceed 1 second. V<sub>OUT</sub> = 0.5V has been chosen to avoid test problems caused by tester ground degradation.

**Notes:**

16. The following values correspond to the CY37512 and CY37384 devices:  $t_{CO} = 5$  ns,  $t_S = 6.5$  ns,  $t_{SCS} = 8.5$  ns,  $t_{ICS} = 8.5$  ns,  $f_{MAX1} = 118$  MHz.

17. The following values correspond to the CY37192V and CY37256V devices:  $t_{CO} = 6$  ns,  $t_S = 7$  ns,  $f_{MAX2} = 143$  MHz,  $f_{MAX3} = 77$  MHz, and  $f_{MAX4} = 100$  MHz; and for the CY37512 devices:  $t_S = 7$  ns.

18. The following values correspond to the CY37512V and CY37384V devices:  $t_{CO} = 6.5$  ns,  $t_S = 9.5$  ns, and  $f_{MAX2} = 105$  MHz.

**Switching Waveforms (continued)**
