
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	PIC
Core Size	8-Bit
Speed	20MHz
Connectivity	I²C, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, POR, PWM, WDT
Number of I/O	25
Program Memory Size	3.5KB (2K x 14)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	128 x 8
Voltage - Supply (Vcc/Vdd)	1.8V ~ 3.6V
Data Converters	A/D 11x8b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	28-SOIC (0.295", 7.50mm Width)
Supplier Device Package	28-SOIC
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic16lf722-i-so

Email: info@E-XFL.COM
Address: Room A, 16/F, Full Win Commercial Centre, 573 Nathan Road, Mongkok, Hong Kong

TABLE 2-1: PIC16(L)F722/3/4/6/7 SPECIAL FUNCTION REGISTER SUMMARY

Address	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Value on: POR, BOR	Page

Legend: x = unknown, u = unchanged, q = value depends on condition, - = unimplemented, read as ‘0’, r = reserved.
Shaded locations are unimplemented, read as ‘0’.

Note 1: The upper byte of the program counter is not directly accessible. PCLATH is a holding register for the PC<12:8>, whose contents are transferred to the upper byte of the program counter.
2: These registers can be addressed from any bank.
3: These registers/bits are not implemented on PIC16F722/723/726/PIC16LF722/723/726 devices, read as ‘0’.
4: Accessible only when SSPM<3:0> = 1001.
5: Accessible only when SSPM<3:0> ≠ 1001.
6: This bit is always ‘1’ as RE3 is input-only.

 © 2007-2015 Microchip Technology Inc.

2.2.2.2 OPTION register

The OPTION register, shown in Register 2-2, is a readable and writable register, which contains various control bits to configure:

- Timer0/WDT prescaler
- External RB0/INT interrupt
- Timer0
- Weak pull-ups on PORTB

> **Note:** To achieve a 1:1 prescaler assignment for Timer0, assign the prescaler to the WDT by setting the PSA bit of the OPTION_REG register to '1'. Refer to **Section 11.1.3 "Software Programmable Prescaler"**.

REGISTER 2-2: OPTION_REG: OPTION REGISTER

4.1 Operation

Interrupts are disabled upon any device Reset. They are enabled by setting the following bits:

- GIE bit of the INTCON register
- Interrupt Enable bit(s) for the specific interrupt event(s)
- PEIE bit of the INTCON register (if the Interrupt Enable bit of the interrupt event is contained in the PIE1 and PIE2 registers)

The INTCON, PIR1 and PIR2 registers record individual interrupts via Interrupt Flag bits. Interrupt Flag bits will be set, regardless of the status of the GIE, PEIE and individual Interrupt Enable bits.

The following events happen when an interrupt event occurs while the GIE bit is set:

- Current prefetched instruction is flushed
- GIE bit is cleared
- Current Program Counter (PC) is pushed onto the stack
- PC is loaded with the interrupt vector 0004h

The ISR determines the source of the interrupt by polling the Interrupt Flag bits. The Interrupt Flag bits must be cleared before exiting the ISR to avoid repeated interrupts. Because the GIE bit is cleared, any interrupt that occurs while executing the ISR will be recorded through its Interrupt Flag, but will not cause the processor to redirect to the interrupt vector.

The `RETFIE` instruction exits the ISR by popping the previous address from the stack and setting the GIE bit.

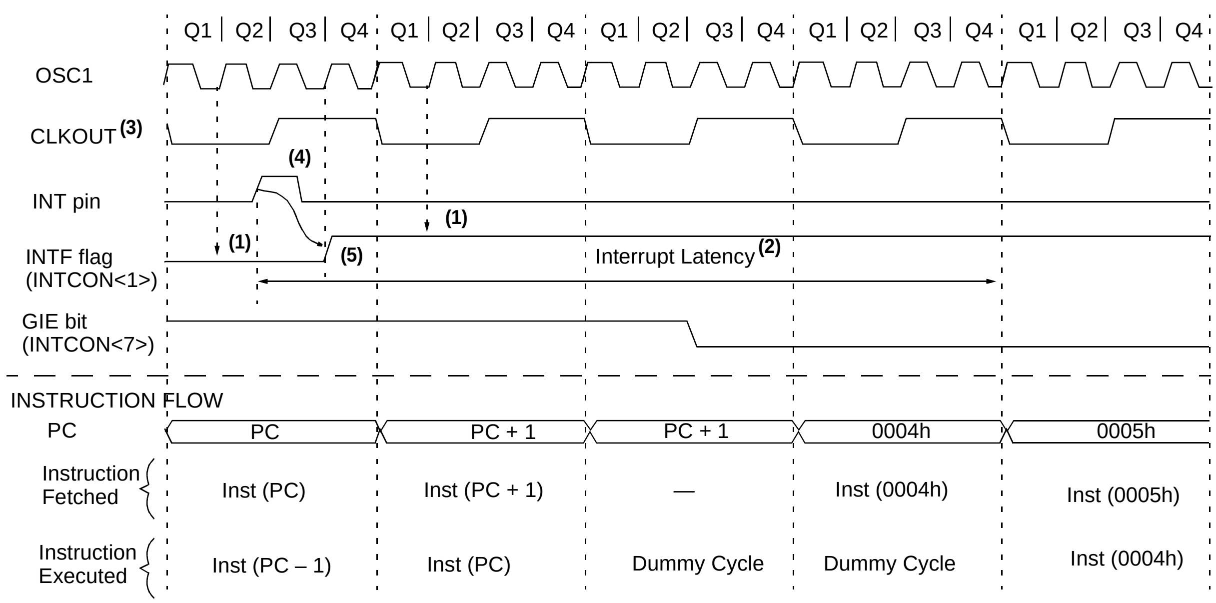
For additional information on a specific interrupt's operation, refer to its peripheral chapter.

Note 1:	Individual Interrupt Flag bits are set, regardless of the state of any other enable bits.
2:	All interrupts will be ignored while the GIE bit is cleared. Any interrupt occurring while the GIE bit is clear will be serviced when the GIE bit is set again.

4.2 Interrupt Latency

Interrupt latency is defined as the time from when the interrupt event occurs to the time code execution at the interrupt vector begins. The latency for synchronous interrupts is three instruction cycles. For asynchronous interrupts, the latency is three to four instruction cycles, depending on when the interrupt occurs. See Figure 4-2 for timing details.

FIGURE 4-2: INT PIN INTERRUPT TIMING



Note 1: INTF flag is sampled here (every Q1).

2: Asynchronous interrupt latency = 3-4 TCY. Synchronous latency = 3 TCY, where TCY = instruction cycle time. Latency is the same whether Inst (PC) is a single cycle or a 2-cycle instruction.

3: CLKOUT is available only in INTOSC and RC Oscillator modes.

4: For minimum width of INT pulse, refer to AC specifications in **Section 23.0 "Electrical Specifications"**.

5: INTF is enabled to be set any time during the Q4-Q1 cycles.

bit 3 **TRISE3:** RE3 Port Tri-state Control bit
This bit is always ‘1’ as RE3 is an input only

bit 2-0 **TRISE<2:0>:** RE<2:0> Tri-State Control bits(1)
1 = PORTE pin configured as an input (tri-stated)
0 = PORTE pin configured as an output

Note 1: TRISE<2:0> are not implemented on the PIC16F722/723/726/PIC16LF722/723/726. Read as ‘0’.

12.1 Timer1 Operation

The Timer1 module is a 16-bit incrementing counter which is accessed through the TMR1H:TMR1L register pair. Writes to TMR1H or TMR1L directly update the counter.

When used with an internal clock source, the module is a timer and increments on every instruction cycle. When used with an external clock source, the module can be used as either a timer or counter and increments on every selected edge of the external source.

Timer1 is enabled by configuring the TMR1ON and TMR1GE bits in the T1CON and T1GCON registers, respectively. Table 12-1 displays the Timer1 enable selections.

TABLE 12-1: TIMER1 ENABLE SELECTIONS

TMR1ON	TMR1GE	Timer1 Operation
0	0	Off
0	1	Off
1	0	Always On
1	1	Count Enabled

12.2 Clock Source Selection

The TMR1CS<1:0> and T1OSCEN bits of the T1CON register are used to select the clock source for Timer1. Table 12-2 displays the clock source selections.

12.2.1 INTERNAL CLOCK SOURCE

When the internal clock source is selected, the TMR1H:TMR1L register pair will increment on multiples of FOSC as determined by the Timer1 prescaler.

12.2.2 EXTERNAL CLOCK SOURCE

When the external clock source is selected, the Timer1 module may work as a timer or a counter.

When enabled to count, Timer1 is incremented on the rising edge of the external clock input T1CKI or the capacitive sensing oscillator signal. Either of these external clock sources can be synchronized to the microcontroller system clock or they can run asynchronously.

When used as a timer with a clock oscillator, an external 32.768 kHz crystal can be used in conjunction with the dedicated internal oscillator circuit.

> **Note:** In Counter mode, a falling edge must be registered by the counter prior to the first incrementing rising edge after any one or more of the following conditions:
> - Timer1 enabled after POR reset
> - Write to TMR1H or TMR1L
> - Timer1 is disabled
> - Timer1 is disabled (TMR1ON = 0) when T1CKI is high then Timer1 is enabled (TMR1ON= 1) when T1CKI is low.

TABLE 12-2: CLOCK SOURCE SELECTIONS

TMR1CS1	TMR1CS0	T1OSCEN	Clock Source
0	1	x	System Clock (FOSC)
0	0	x	Instruction Clock (FOSC/4)
1	1	x	Capacitive Sensing Oscillator
1	0	0	External Clocking on T1CKI Pin
1	0	1	Oscillator Circuit on T1OSI/T1OSO Pins

© 2007-2015 Microchip Technology Inc.

12.6 Timer1 Gate

Timer1 can be configured to count freely or the count can be enabled and disabled using Timer1 Gate circuitry. This is also referred to as Timer1 Gate Count Enable.

Timer1 Gate can also be driven by multiple selectable sources.

12.6.1 TIMER1 GATE COUNT ENABLE

The Timer1 Gate is enabled by setting the TMR1GE bit of the T1GCON register. The polarity of the Timer1 Gate is configured using the T1GPOL bit of the T1GCON register.

When Timer1 Gate (T1G) input is active, Timer1 will increment on the rising edge of the Timer1 clock source. When Timer1 Gate input is inactive, no incrementing will occur and Timer1 will hold the current count. See Figure 12-3 for timing details.

TABLE 12-3: TIMER1 GATE ENABLE SELECTIONS

T1CLK	T1GPOL	T1G	Timer1 Operation
↑	0	0	Counts
↑	0	1	Holds Count
↑	1	0	Holds Count
↑	1	1	Counts

12.6.2 TIMER1 GATE SOURCE SELECTION

The Timer1 Gate source can be selected from one of four different sources. Source selection is controlled by the T1GSS bits of the T1GCON register. The polarity for each available source is also selectable. Polarity selection is controlled by the T1GPOL bit of the T1GCON register.

TABLE 12-4: TIMER1 GATE SOURCES

T1GSS	Timer1 Gate Source
00	Timer1 Gate Pin
01	Overflow of Timer0 (TMR0 increments from FFh to 00h)
10	Timer2 match PR2 (TMR2 increments to match PR2)
11	Count Enabled by WDT Overflow (Watchdog Time-out interval expired)

12.6.2.1 T1G Pin Gate Operation

The T1G pin is one source for Timer1 Gate Control. It can be used to supply an external source to the Timer1 Gate circuitry.

12.6.2.2 Timer0 Overflow Gate Operation

When Timer0 increments from FFh to 00h, a low-to-high pulse will automatically be generated and internally supplied to the Timer1 Gate circuitry.

12.6.2.3 Timer2 Match Gate Operation

The TMR2 register will increment until it matches the value in the PR2 register. On the very next increment cycle, TMR2 will be reset to 00h. When this Reset occurs, a low-to-high pulse will automatically be generated and internally supplied to the Timer1 Gate circuitry.

12.6.2.4 Watchdog Overflow Gate Operation

The Watchdog Timer oscillator, prescaler and counter will be automatically turned on when TMR1GE = 1 and T1GSS selects the WDT as a gate source for Timer1 (T1GSS = 11). TMR1ON does not factor into the oscillator, prescaler and counter enable. See Table 12-5.

The PSA and PS bits of the OPTION register still control what time-out interval is selected. Changing the prescaler during operation may result in a spurious capture.

Enabling the Watchdog Timer oscillator does not automatically enable a Watchdog Reset or Wake-up from Sleep upon counter overflow.

Note:	When using the WDT as a gate source for Timer1, operations that clear the Watchdog Timer (CLRWDT, SLEEP instructions) will affect the time interval being measured for capacitive sensing. This includes waking from Sleep. All other interrupts that might wake the device from Sleep should be disabled to prevent them from disturbing the measurement period.

As the gate signal coming from the WDT counter will generate different pulse widths depending on if the WDT is enabled, when the CLRWDT instruction is executed, and so on, Toggle mode must be used. A specific sequence is required to put the device into the correct state to capture the next WDT counter interval.

© 2007-2015 Microchip Technology Inc.

12.11 Timer1 Control Register

The Timer1 Control register (T1CON), shown in Register 12-1, is used to control Timer1 and select the various features of the Timer1 module.

REGISTER 12-1: T1CON: TIMER1 CONTROL REGISTER

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	U-0	R/W-0
TMR1CS1	TMR1CS0	T1CKPS1	T1CKPS0	T1OSCEN	$\overline{\text{T1SYNC}}$	—	TMR1ON
bit 7							bit 0

Legend:			
R = Readable bit	W = Writable bit	U = Unimplemented bit, read as ‘0’	
-n = Value at POR	‘1’ = Bit is set	‘0’ = Bit is cleared	x = Bit is unknown

bit 7-6 **TMR1CS<1:0>:** Timer1 Clock Source Select bits
11 = Timer1 clock source is Capacitive Sensing Oscillator (CAPOSC)
10 = Timer1 clock source is pin or oscillator:
If T1OSCEN = 0:
External clock from T1CKI pin (on the rising edge)
If T1OSCEN = 1:
Crystal oscillator on T1OSI/T1OSO pins
01 = Timer1 clock source is system clock (FOSC)
00 = Timer1 clock source is instruction clock (FOSC/4)

bit 5-4 **T1CKPS<1:0>:** Timer1 Input Clock Prescale Select bits
11 = 1:8 Prescale value
10 = 1:4 Prescale value
01 = 1:2 Prescale value
00 = 1:1 Prescale value

bit 3 **T1OSCEN:** LP Oscillator Enable Control bit
1 = Dedicated Timer1 oscillator circuit enabled
0 = Dedicated Timer1 oscillator circuit disabled

bit 2 **$\overline{\text{T1SYNC}}$:** Timer1 External Clock Input Synchronization Control bit
TMR1CS<1:0> = 1X
1 = Do not synchronize external clock input
0 = Synchronize external clock input with system clock (FOSC)

TMR1CS<1:0> = 0X
This bit is ignored. Timer1 uses the internal clock when TMR1CS<1:0> = 1X.

bit 1 **Unimplemented:** Read as ‘0’

bit 0 **TMR1ON:** Timer1 On bit
1 = Enables Timer1
0 = Stops Timer1
Clears Timer1 Gate flip-flop

15.2 Compare Mode

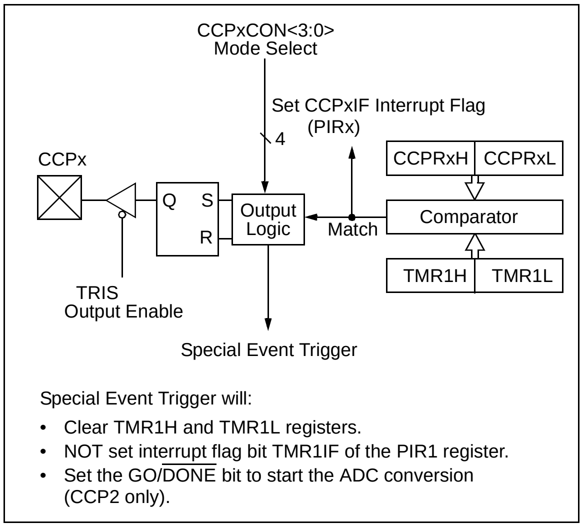
In Compare mode, the 16-bit CCPRx register value is constantly compared against the TMR1 register pair value. When a match occurs, the CCPx module may:

- Toggle the CCPx output
- Set the CCPx output
- Clear the CCPx output
- Generate a Special Event Trigger
- Generate a Software Interrupt

The action on the pin is based on the value of the CCPxM<3:0> control bits of the CCPxCON register.

All Compare modes can generate an interrupt.

FIGURE 15-2: COMPARE MODE OPERATION BLOCK DIAGRAM



15.2.1 CCPx PIN CONFIGURATION

The user must configure the CCPx pin as an output by clearing the associated TRIS bit.

Either RC1 or RB3 can be selected as the CCP2 pin. Refer to **Section 6.1 "Alternate Pin Function"** for more information.

Note:	Clearing the CCPxCON register will force the CCPx compare output latch to the default low level. This is not the PORT I/O data latch.

15.2.2 TIMER1 MODE SELECTION

In Compare mode, Timer1 must be running in either Timer mode or Synchronized Counter mode. The compare operation may not work in Asynchronous Counter mode.

Note:	Clocking Timer1 from the system clock (FOSC) should not be used in Compare mode. For the Compare operation of the TMR1 register to the CCPRx register to occur, Timer1 must be clocked from the Instruction Clock (FOSC/4) or from an external clock source.

15.2.3 SOFTWARE INTERRUPT MODE

When Software Interrupt mode is chosen (CCPxM<3:0> = `1010`), the CCPxIF bit in the PIRx register is set and the CCPx module does not assert control of the CCPx pin (refer to the CCPxCON register).

15.2.4 SPECIAL EVENT TRIGGER

When Special Event Trigger mode is chosen (CCPxM<3:0> = `1011`), the CCPx module does the following:

- Resets Timer1
- Starts an ADC conversion if ADC is enabled (CCP2 only)

The CCPx module does not assert control of the CCPx pin in this mode (refer to the CCPxCON register).

The Special Event Trigger output of the CCP occurs immediately upon a match between the TMR1H, TMR1L register pair and the CCPRxH, CCPRxL register pair. The TMR1H, TMR1L register pair is not reset until the next rising edge of the Timer1 clock. This allows the CCPRxH, CCPRxL register pair to effectively provide a 16-bit programmable period register for Timer1.

Note 1:	The Special Event Trigger from the CCP module does not set interrupt flag bit TMR1IF of the PIR1 register.
2:	Removing the match condition by changing the contents of the CCPRxH and CCPRxL register pair, between the clock edge that generates the Special Event Trigger and the clock edge that generates the Timer1 Reset, will preclude the Reset from occurring.

15.2.5 COMPARE DURING SLEEP

The Compare Mode is dependent upon the system clock (FOSC) for proper operation. Since FOSC is shut down during Sleep mode, the Compare mode will not function properly during Sleep.

© 2007-2015 Microchip Technology Inc.

16.1 AUSART Asynchronous Mode

The AUSART transmits and receives data using the standard non-return-to-zero (NRZ) format. NRZ is implemented with two levels: a V_{OH} Mark state which represents a '1' data bit, and a V_{OL} Space state which represents a '0' data bit. NRZ refers to the fact that consecutively transmitted data bits of the same value stay at the output level of that bit without returning to a neutral level between each bit transmission. An NRZ transmission port idles in the Mark state. Each character transmission consists of one Start bit followed by eight or nine data bits and is always terminated by one or more Stop bits. The Start bit is always a space and the Stop bits are always marks. The most common data format is 8 bits. Each transmitted bit persists for a period of 1/(Baud Rate). An on-chip dedicated 8-bit Baud Rate Generator is used to derive standard baud rate frequencies from the system oscillator. Refer to Table 16-5 for examples of baud rate Configurations.

The AUSART transmits and receives the LSb first. The AUSART's transmitter and receiver are functionally independent, but share the same data format and baud rate. Parity is not supported by the hardware, but can be implemented in software and stored as the ninth data bit.

16.1.1 AUSART ASYNCHRONOUS TRANSMITTER

The AUSART transmitter block diagram is shown in Figure 16-1. The heart of the transmitter is the serial Transmit Shift Register (TSR), which is not directly accessible by software. The TSR obtains its data from the transmit buffer, which is the TXREG register.

16.1.1.1 Enabling the Transmitter

The AUSART transmitter is enabled for asynchronous operations by configuring the following three control bits:

- TXEN = 1
- SYNC = 0
- SPEN = 1

All other AUSART control bits are assumed to be in their default state.

Setting the TXEN bit of the TXSTA register enables the transmitter circuitry of the AUSART. Clearing the SYNC bit of the TXSTA register configures the AUSART for asynchronous operation. Setting the SPEN bit of the RCSTA register enables the AUSART and automatically configures the TX/CK I/O pin as an output.

Note 1:	When the SPEN bit is set the RX/DT I/O pin is automatically configured as an input, regardless of the state of the corresponding TRIS bit and whether or not the AUSART receiver is enabled. The RX/DT pin data can be read via a normal PORT read but PORT latch data output is precluded.
2:	The TXIF transmitter interrupt flag is set when the TXEN enable bit is set.

16.1.1.2 Transmitting Data

A transmission is initiated by writing a character to the TXREG register. If this is the first character, or the previous character has been completely flushed from the TSR, the data in the TXREG is immediately transferred to the TSR register. If the TSR still contains all or part of a previous character, the new character data is held in the TXREG until the Stop bit of the previous character has been transmitted. The pending character in the TXREG is then transferred to the TSR in one T_{CY} immediately following the Stop bit transmission. The transmission of the Start bit, data bits and Stop bit sequence commences immediately following the transfer of the data to the TSR from the TXREG.

16.1.1.3 Transmit Interrupt Flag

The TXIF interrupt flag bit of the PIR1 register is set whenever the AUSART transmitter is enabled and no character is being held for transmission in the TXREG. In other words, the TXIF bit is only clear when the TSR is busy with a character and a new character has been queued for transmission in the TXREG. The TXIF flag bit is not cleared immediately upon writing TXREG. TXIF becomes valid in the second instruction cycle following the write execution. Polling TXIF immediately following the TXREG write will return invalid results. The TXIF bit is read-only, it cannot be set or cleared by software.

The TXIF interrupt can be enabled by setting the TXIE interrupt enable bit of the PIE1 register. However, the TXIF flag bit will be set whenever the TXREG is empty, regardless of the state of TXIE enable bit.

To use interrupts when transmitting data, set the TXIE bit only when there is more data to send. Clear the TXIE interrupt enable bit upon writing the last character of the transmission to the TXREG.

REGISTER 16-1: TXSTA: TRANSMIT STATUS AND CONTROL REGISTER

R/W-0	R/W-0	R/W-0	R/W-0	U-0	R/W-0	R-1	R/W-0
CSRC	TX9	TXEN(1)	SYNC	—	BRGH	TRMT	TX9D
bit 7							bit 0

Legend:			
R = Readable bit	W = Writable bit	U = Unimplemented bit, read as ‘0’	
-n = Value at POR	‘1’ = Bit is set	‘0’ = Bit is cleared	x = Bit is unknown

bit 7 **CSRC:** Clock Source Select bit
Asynchronous mode:
Don’t care
Synchronous mode:
1 = Master mode (clock generated internally from BRG)
0 = Slave mode (clock from external source)

bit 6 **TX9:** 9-bit Transmit Enable bit
1 = Selects 9-bit transmission
0 = Selects 8-bit transmission

bit 5 **TXEN:** Transmit Enable bit(1)
1 = Transmit enabled
0 = Transmit disabled

bit 4 **SYNC:** AUSART Mode Select bit
1 = Synchronous mode
0 = Asynchronous mode

bit 3 **Unimplemented:** Read as ‘0’

bit 2 **BRGH:** High Baud Rate Select bit
Asynchronous mode:
1 = High speed
0 = Low speed
Synchronous mode:
Unused in this mode

bit 1 **TRMT:** Transmit Shift Register Status bit
1 = TSR empty
0 = TSR full

bit 0 **TX9D:** Ninth bit of Transmit Data
Can be address/data bit or a parity bit.

Note 1: SREN/CREN overrides TXEN in Synchronous mode.

17.2 I^{2}C Mode

The SSP module, in I^{2}C mode, implements all slave functions, except general call support. It provides interrupts on Start and Stop bits in hardware to facilitate firmware implementations of the master functions. The SSP module implements the I^{2}C Standard mode specifications:

- I^{2}C Slave mode (7-bit address)
- I^{2}C Slave mode (10-bit address)
- Start and Stop bit interrupts enabled to support firmware Master mode
- Address masking

Two pins are used for data transfer; the SCL pin (clock line) and the SDA pin (data line). The user must configure the two pin's data direction bits as inputs in the appropriate TRIS register. Upon enabling I^{2}C mode, the I^{2}C slew rate limiters in the I/O pads are controlled by the SMP bit of SSPSTAT register. The SSP module functions are enabled by setting the SSPEN bit of SSPCON register.

Data is sampled on the rising edge and shifted out on the falling edge of the clock. This ensures that the SDA signal is valid during the SCL high time. The SCL clock input must have minimum high and low times for proper operation. Refer to **Section 23.0 "Electrical Specifications"**.

FIGURE 17-7: I^{2}C MODE BLOCK DIAGRAM

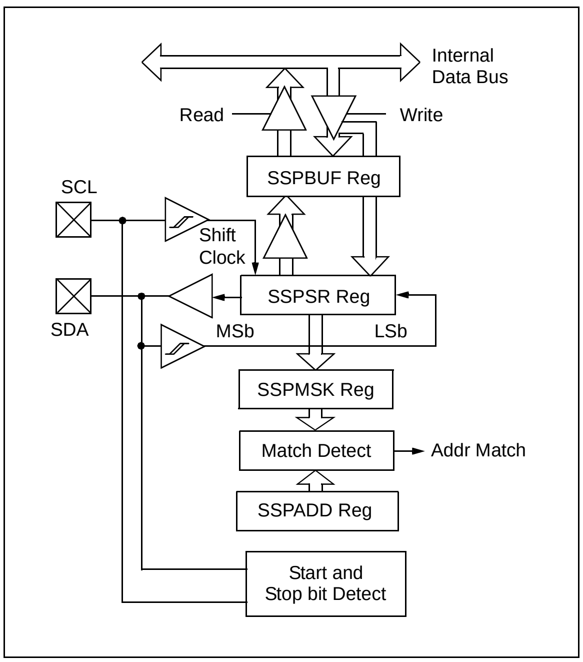

FIGURE 17-8: TYPICAL I^{2}C CONNECTIONS

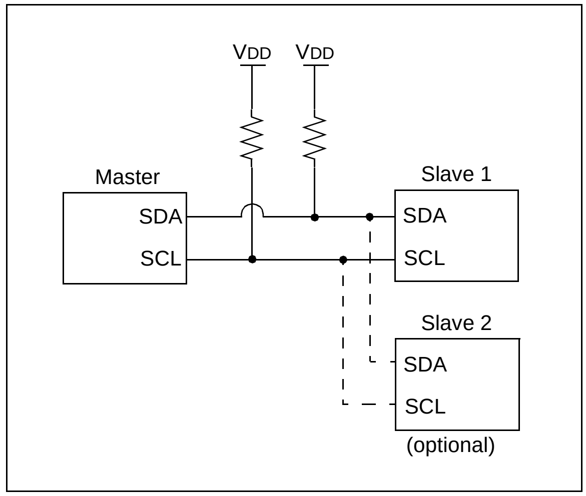

The SSP module has six registers for I^{2}C operation. They are:

- SSP Control (SSPCON) register
- SSP Status (SSPSTAT) register
- Serial Receive/Transmit Buffer (SSPBUF) register
- SSP Shift Register (SSPSR), not directly accessible
- SSP Address (SSPADD) register
- SSP Address Mask (SSPMSK) register

17.2.1 HARDWARE SETUP

Selection of I^{2}C mode, with the SSPEN bit of the SSPCON register set, forces the SCL and SDA pins to be open drain, provided these pins are programmed as inputs by setting the appropriate TRISC bits. The SSP module will override the input state with the output data, when required, such as for Acknowledge and slave-transmitter sequences.

Note:	Pull-up resistors must be provided externally to the SCL and SDA pins for proper operation of the I^{2}C module

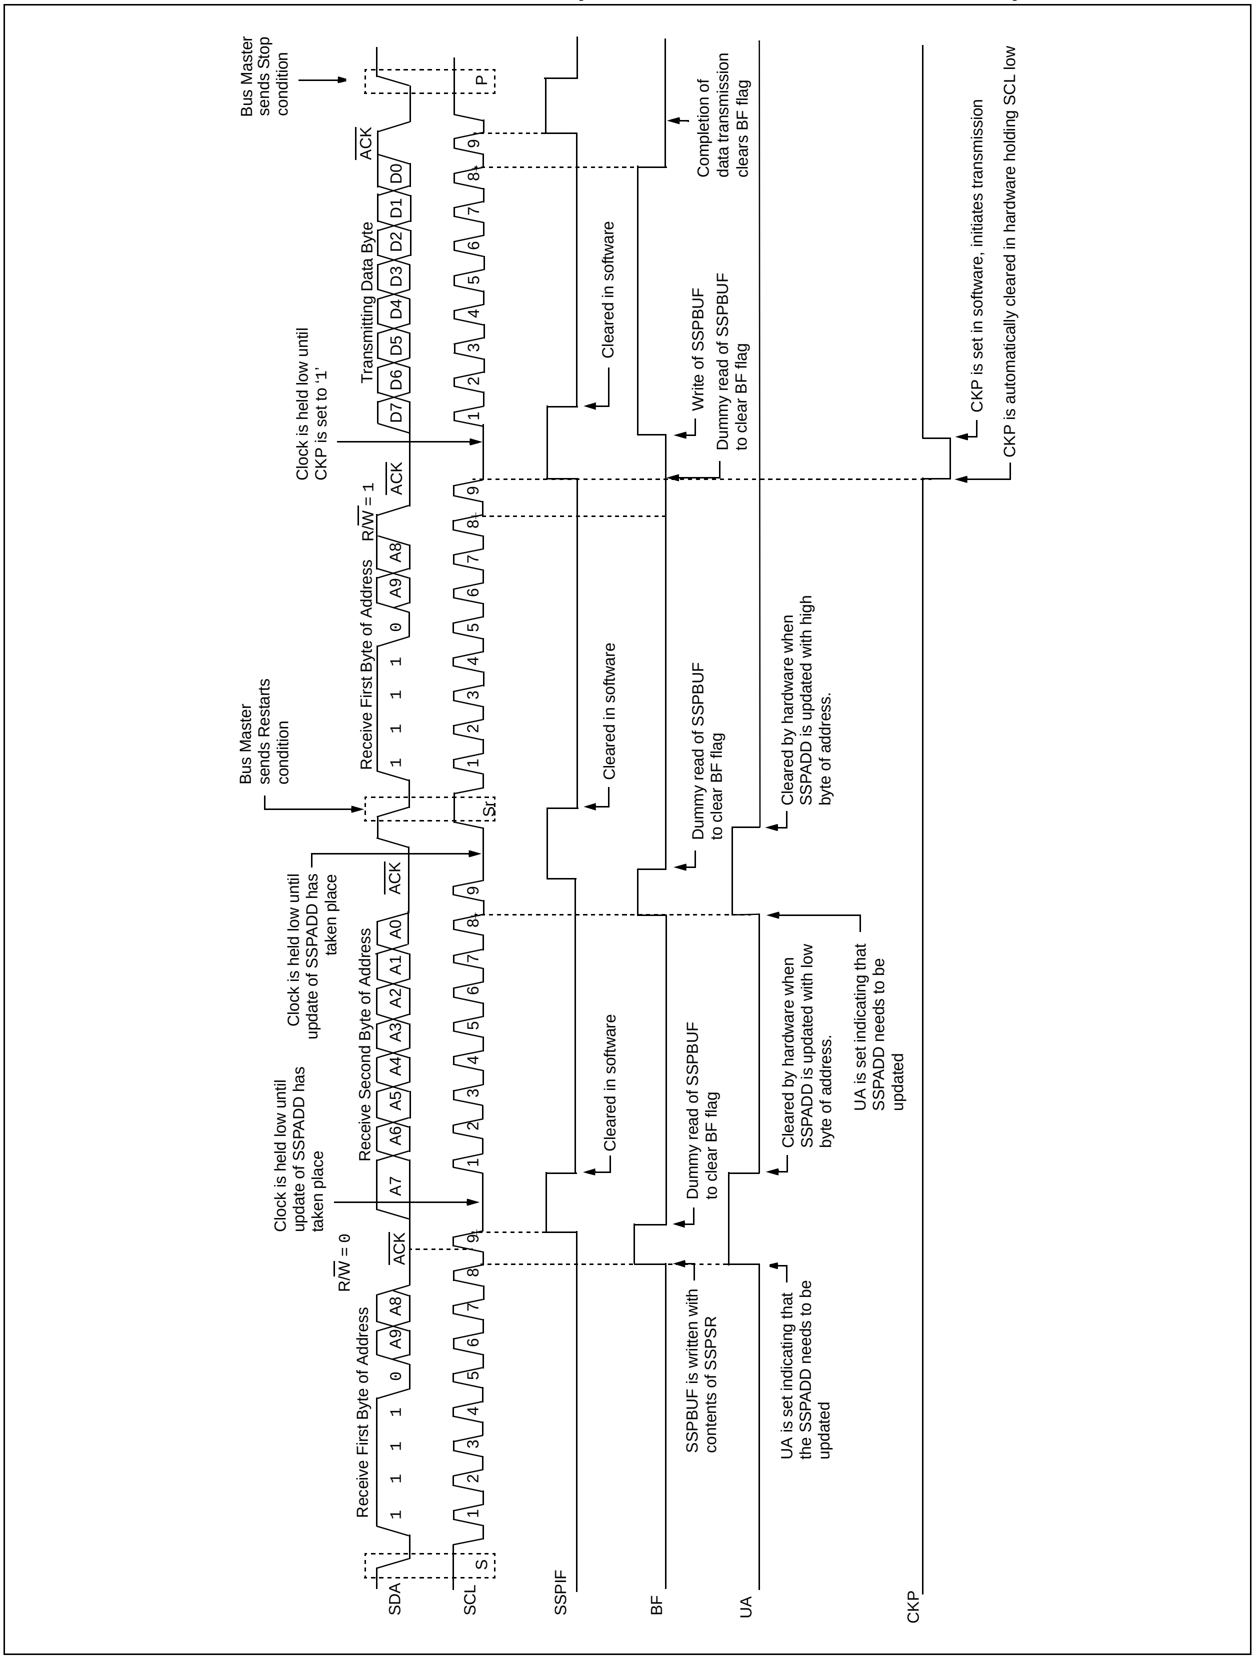
FIGURE 17-13: I²C SLAVE MODE TIMING (TRANSMISSION 10-BIT ADDRESS)



17.2.10 CLOCK SYNCHRONIZATION

When the CKP bit is cleared, the SCL output is held low once it is sampled low. therefore, the CKP bit will not stretch the SCL line until an external I^{2}C master device has already asserted the SCL line low. The SCL output will remain low until the CKP bit is set and all other devices on the I^{2}C bus have released SCL. This ensures that a write to the CKP bit will not violate the minimum high time requirement for SCL (Figure 17-14).

17.2.11 SLEEP OPERATION

While in Sleep mode, the I^{2}C module can receive addresses of data, and when an address match or complete byte transfer occurs, wake the processor from Sleep (if SSP interrupt is enabled).

		—	2.0	2.8	mA	3.6	
D019		—	1.6	2	mA	3.0	FOSC = 20 MHz HS Oscillator mode **(Note 5)**
		—	1.9	3.2	mA	5.0	

Note 1: The test conditions for all IDD measurements in active operation mode are: OSC1 = external square wave, from rail-to-rail; all I/O pins tri-stated, pulled to VDD; $\overline{MCLR}$ = VDD; WDT disabled.

2: The supply current is mainly a function of the operating voltage and frequency. Other factors, such as I/O pin loading and switching rate, oscillator type, internal code execution pattern and temperature, also have an impact on the current consumption.

3: For RC oscillator configurations, current through REXT is not included. The current through the resistor can be extended by the formula IR = VDD/2REXT (mA) with REXT in kΩ.

4: FVR and BOR are disabled.

5: 0.1 μF capacitor on VCAP (RA0).

Legend: TBD = To Be Determined
* These parameters are characterized but not tested.
† Data in "Typ" column is at 3.0V, 25°C unless otherwise stated. These parameters are for design guidance only and are not tested.

Note 1: In RC oscillator configuration, the OSC1/CLKIN pin is a Schmitt Trigger input. It is not recommended to use an external clock in RC mode.
2: Negative current is defined as current sourced by the pin.
3: The leakage current on the $\overline{MCLR}$ pin is strongly dependent on the applied voltage level. The specified levels represent normal operating conditions. Higher leakage current may be measured at different input voltages.
4: Including OSC2 in CLKOUT mode.
