
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Obsolete
Core Processor	eZ8
Core Size	8-Bit
Speed	5MHz
Connectivity	IrDA, UART/USART
Peripherals	Brown-out Detect/Reset, LED, POR, PWM, WDT
Number of I/O	6
Program Memory Size	8KB (8K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	1K x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 3.6V
Data Converters	-
Oscillator Type	Internal
Operating Temperature	-40°C ~ 105°C (TA)
Mounting Type	Surface Mount
Package / Case	8-VDFN Exposed Pad
Supplier Device Package	8-QFN (5x6)
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z8f0813qb005ec

Overview

Zilog's Z8 Encore! XP® microcontroller unit (MCU) family of products are the first Zilog® microcontroller products based on the 8-bit eZ8 CPU core. Z8 Encore! XP F0823 Series products expand upon Zilog's extensive line of 8-bit microcontrollers. The Flash in-circuit programming capability allows for faster development time and program changes in the field. The new eZ8 CPU is upward compatible with existing Z8® instructions. The rich peripheral set of Z8 Encore! XP F0823 Series makes it suitable for a variety of applications including motor control, security systems, home appliances, personal electronic devices, and sensors.

Features

The key features of Z8 Encore! XP F0823 Series include:

- 5 MHz eZ8 CPU
- 1 KB, 2 KB, 4 KB, or 8 KB Flash memory with in-circuit programming capability
- 256 B, 512 B, or 1 KB register RAM
- 6 to 24 I/O pins depending upon package
- Internal precision oscillator (IPO)
- Full-duplex UART
- The universal asynchronous receiver/transmitter (UART) baud rate generator (BRG) can be configured and used as a basic 16-bit timer
- Infrared data association (IrDA)-compliant infrared encoder/decoders, integrated with UART
- Two enhanced 16-bit timers with capture, compare, and PWM capability
- Watchdog Timer (WDT) with dedicated internal RC oscillator
- On-Chip Debugger (OCD)
- Optional 8-channel, 10-bit Analog-to-Digital Converter (ADC)
- On-Chip analog comparator
- Up to 20 vectored interrupts
- Direct LED drive with programmable drive strengths
- Voltage Brownout (VBO) protection
- Power-On Reset (POR)

Block Diagram

Figure 1 on page 3 displays the block diagram of the architecture of Z8 Encore! XP F0823 Series devices.

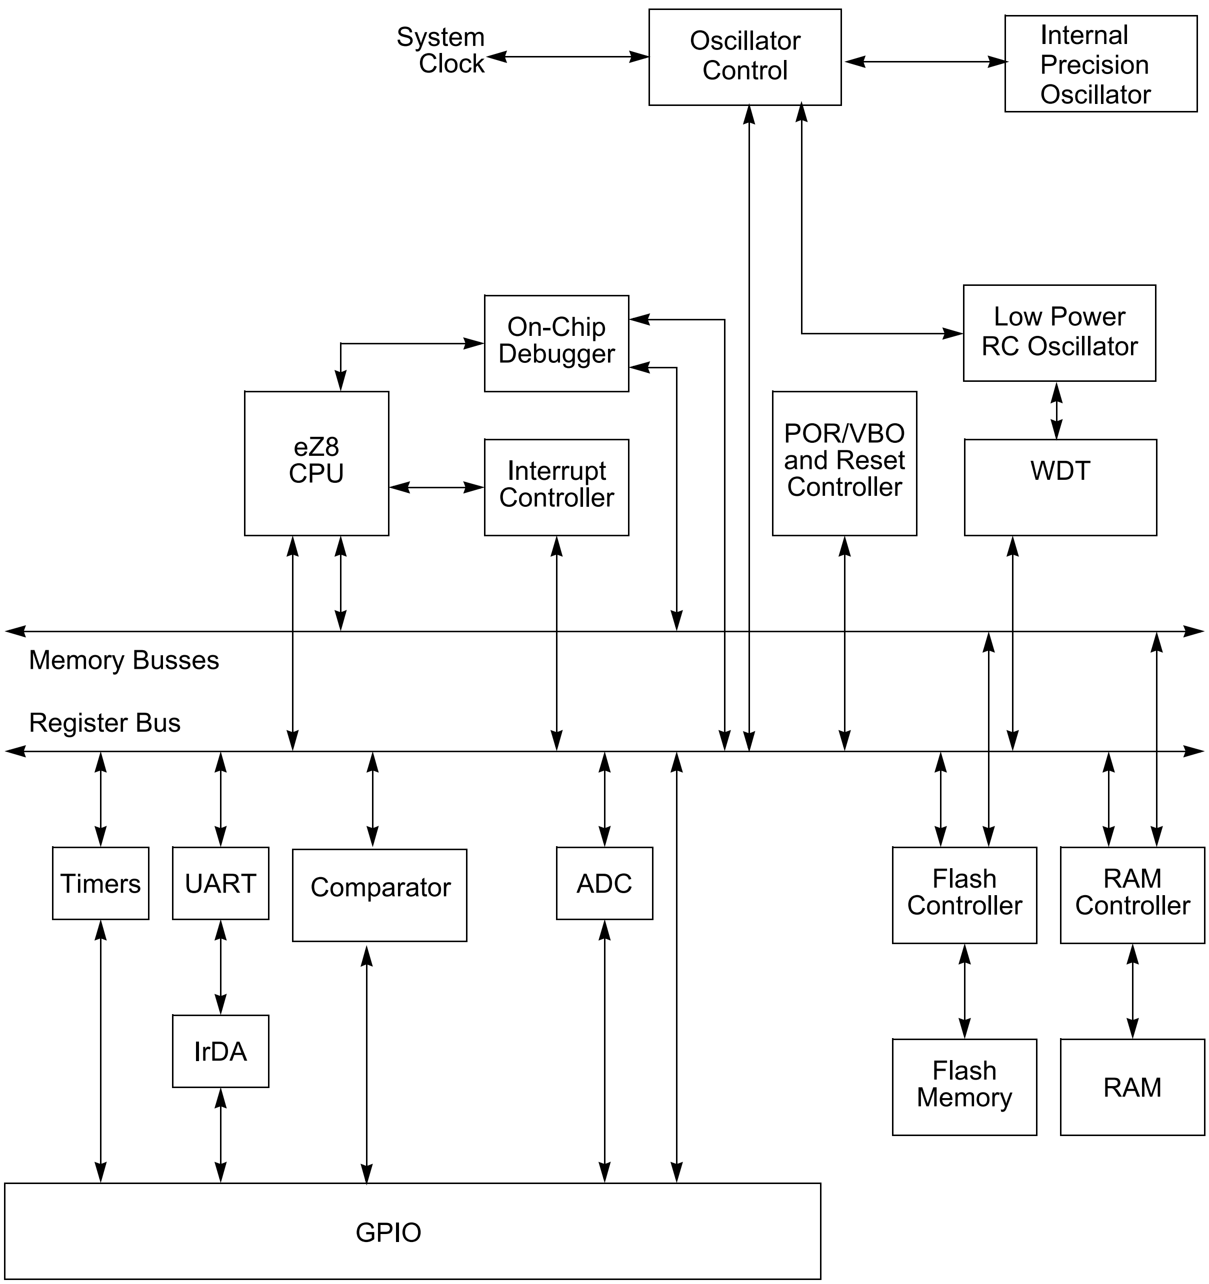

Figure 1. Z8 Encore! XP® F0823 Series Block Diagram

Table 15. Port Alternate Function Mapping (Non 8-Pin Parts)

Port	Pin	Mnemonic	Alternate Function Description	Alternate Function Set Register AFS1
Port A	PA0	T0IN/$\overline{\text{T0OUT}}$*	Timer 0 Input/Timer 0 Output Complement	N/A
		Reserved		
	PA1	T0OUT	Timer 0 Output	
		Reserved		
	PA2	DE0	UART 0 Driver Enable	
		Reserved		
	PA3	$\overline{\text{CTS0}}$	UART 0 Clear to Send	
		Reserved		
	PA4	RXD0/IRRX0	UART 0 / IrDA 0 Receive Data	
		Reserved		
	PA5	TXD0/IRTX0	UART 0 / IrDA 0 Transmit Data	
		Reserved		
	PA6	T1IN/$\overline{\text{T1OUT}}$*	Timer 1 Input/Timer 1 Output Complement	
		Reserved		
	PA7	T1OUT	Timer 1 Output	
		Reserved		

Note: Because there is only a single alternate function for each Port A pin, the Alternate Function Set registers are not implemented for Port A. Enabling alternate function selections as described in Port A–C Alternate Function Sub-Registers automatically enables the associated alternate function.
* Whether PA0/PA6 take on the timer input or timer output complement function depends on the timer configuration as described in Timer Pin Signal Operation on page 79.

3. Clears the UART Receiver interrupt in the applicable Interrupt Request register.
4. Executes the `IRET` instruction to return from the interrupt-service routine and await more data.

Clear To Send ($\overline{\text{CTS}}$) Operation

The CTS pin, if enabled by the CTSE bit of the UART Control 0 register, performs flow control on the outgoing transmit datastream. The Clear To Send ($\overline{\text{CTS}}$) input pin is sampled one system clock before beginning any new character transmission. To delay transmission of the next data character, an external receiver must deassert $\overline{\text{CTS}}$ at least one system clock cycle before a new data transmission begins. For multiple character transmissions, this action is typically performed during Stop Bit transmission. If $\overline{\text{CTS}}$ deasserts in the middle of a character transmission, the current character is sent completely.

MULTIPROCESSOR (9-Bit) Mode

The UART has a MULTIPROCESSOR (9-bit) mode that uses an extra (9^{th}) bit for selective communication when a number of processors share a common UART bus. In MULTIPROCESSOR mode (also referred to as 9-bit mode), the multiprocessor bit (`MP`) is transmitted immediately following the 8-bits of data and immediately preceding the Stop bit(s) as displayed in Figure 13. The character format is given below:

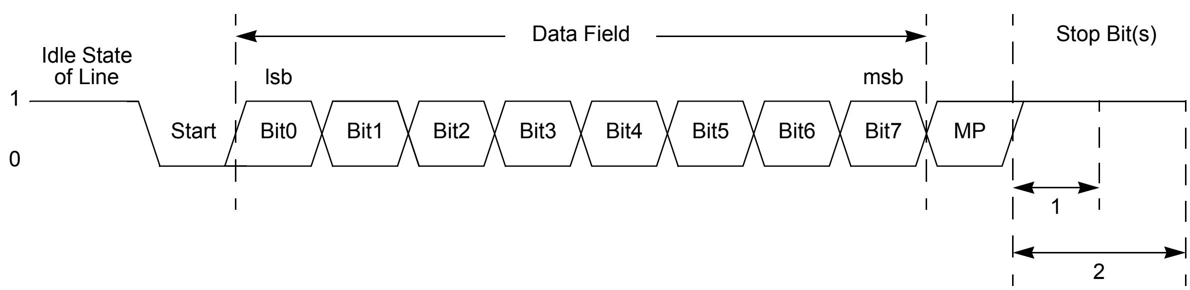

Figure 13. UART Asynchronous MULTIPROCESSOR Mode Data Format

In MULTIPROCESSOR (9-bit) mode, the Parity bit location (9^{th} bit) becomes the Multiprocessor control bit. The UART Control 1 and Status 1 registers provide MULTIPROCESSOR (9-bit) mode control and status information. If an automatic address matching scheme is enabled, the UART Address Compare register holds the network address of the device.

MULTIPROCESSOR (9-bit) Mode Receive Interrupts

When MULTIPROCESSOR mode is enabled, the UART only processes frames addressed to it. The determination of whether a frame of data is addressed to the UART can be made

External Driver Enable

The UART provides a Driver Enable (DE) signal for off-chip bus transceivers. This feature reduces the software overhead associated with using a GPIO pin to control the transceiver when communicating on a multi-transceiver bus, such as RS-485.

Driver Enable is an active High signal that envelopes the entire transmitted data frame including parity and Stop bits as displayed in Figure 14. The Driver Enable signal asserts when a byte is written to the UART Transmit Data register. The Driver Enable signal asserts at least one UART bit period and no greater than two UART bit periods before the Start bit is transmitted. This allows a setup time to enable the transceiver. The Driver Enable signal deasserts one system clock period after the final Stop bit is transmitted. This one system clock delay allows both time for data to clear the transceiver before disabling it, as well as the ability to determine if another character follows the current character. In the event of back to back characters (new data must be written to the Transmit Data Register before the previous character is completely transmitted) the DE signal is not deasserted between characters. The `DEPOL` bit in the UART Control Register 1 sets the polarity of the Driver Enable signal.

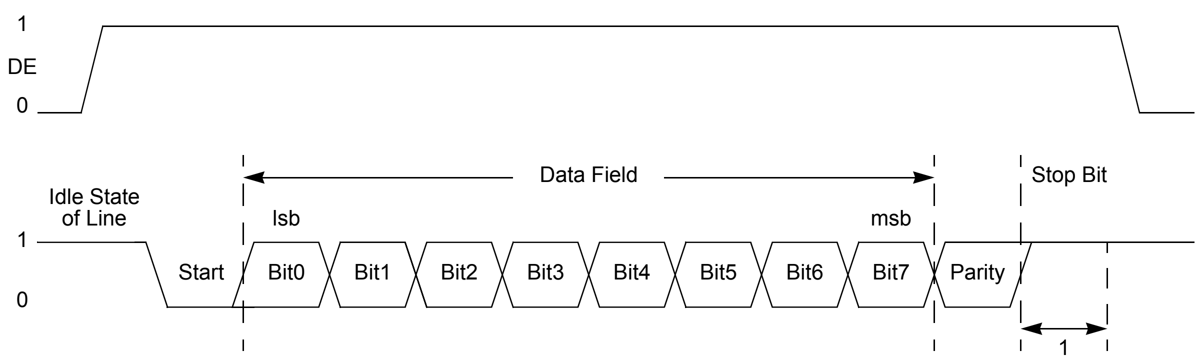

Figure 14. UART Driver Enable Signal Timing (shown with 1 Stop Bit and Parity)

The Driver Enable to Start bit setup time is calculated as follows:

$$\left(\frac{1}{\text{Baud Rate (Hz)}}\right) \le \text{DE to Start Bit Setup Time (s)} \le \left(\frac{2}{\text{Baud Rate (Hz)}}\right)$$

UART Interrupts

The UART features separate interrupts for the transmitter and the receiver. In addition, when the UART primary functionality is disabled, the Baud Rate Generator can also function as a basic timer with interrupt capability.

(BRG[15:0]) that sets the data transmission rate (baud rate) of the UART. The UART data rate is calculated using the following equation:

$$\text{UART Data Rate (bits/s)} = \frac{\text{System Clock Frequency (Hz)}}{16 \times \text{UART Baud Rate Divisor Value}}$$

When the UART is disabled, the Baud Rate Generator functions as a basic 16-bit timer with interrupt on time-out. Follow the steps below to configure the Baud Rate Generator as a timer with interrupt on time-out:

1. Disable the UART by clearing the REN and TEN bits in the UART Control 0 register to 0.
2. Load the acceptable 16-bit count value into the UART Baud Rate High and Low Byte registers.
3. Enable the Baud Rate Generator timer function and associated interrupt by setting the `BIRQ` bit in the UART Control 1 register to 1.

When configured as a general purpose timer, the interrupt interval is calculated using the following equation:

$$\text{Interrupt Interval (s)} = \text{System Clock Period (s)} \times \text{BRG[15:0]}$$

UART Control Register Definitions

The UART control registers support the UART and the associated Infrared Encoder/Decoders. For more information on the infrared operation, see Infrared Encoder/Decoder on page 113.

UART Transmit Data Register

Data bytes written to the UART Transmit Data register (Table 62) are shifted out on the `TXDx` pin. The Write-only UART Transmit Data register shares a Register File address with the read-only UART Receive Data register.

Table 62. UART Transmit Data Register (U0TXD)

BITS	7	6	5	4	3	2	1	0
FIELD	TXD							
RESET	X	X	X	X	X	X	X	X
R/W	W	W	W	W	W	W	W	W
ADDR	F40H							

TXD—Transmit Data
UART transmitter data byte to be shifted out through the TXD*x* pin.

Receiving IrDA Data

Data received from the infrared transceiver using the IR_RXD signal through the RXD pin is decoded by the Infrared Endec and passed to the UART. The UART's baud rate clock is used by the Infrared Endec to generate the demodulated signal (RXD) that drives the UART. Each UART/Infrared data bit is 16-clocks wide. Figure 18 displays data reception. When the Infrared Endec is enabled, the UART's RXD signal is internal to the Z8 Encore! XP® F0823 Series products while the IR_RXD signal is received through the RXD pin.

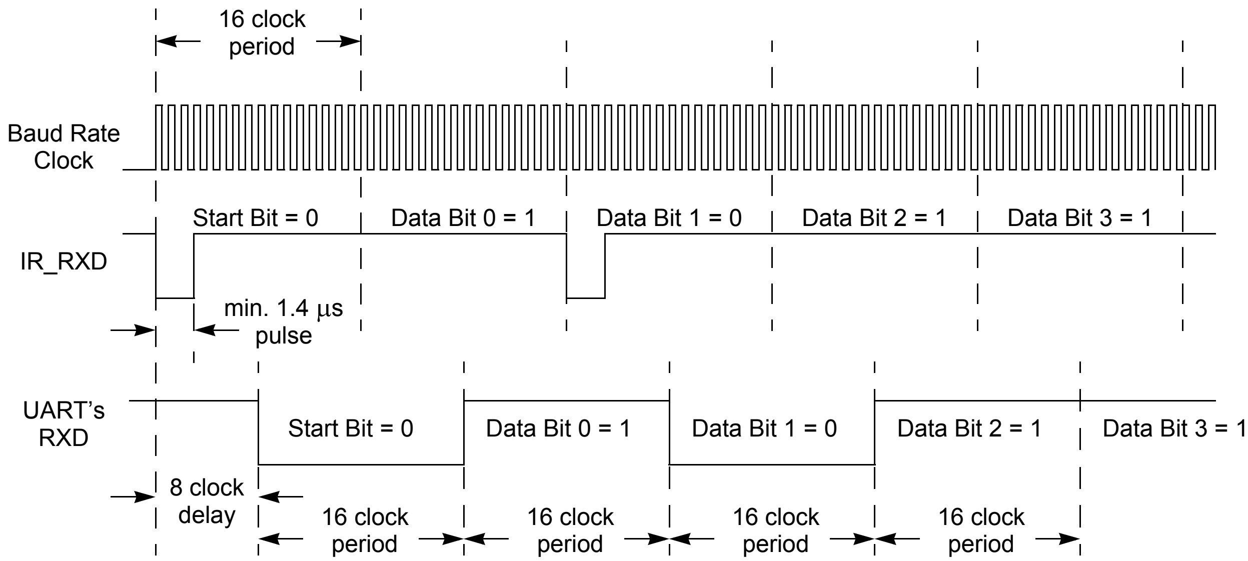

Figure 18. IrDA Data Reception

Infrared Data Reception

! **Caution:** *The system clock frequency must be at least 1.0 MHz to ensure proper reception of the 1.4 µs minimum width pulses allowed by the IrDA standard.*

Endec Receiver Synchronization

The IrDA receiver uses a local baud rate clock counter (0 to 15 clock periods) to generate an input stream for the UART and to create a sampling window for detection of incoming pulses. The generated UART input (UART RXD) is delayed by 8 baud rate clock periods with respect to the incoming IrDA data stream. When a falling edge in the input data stream is detected, the Endec counter is reset. When the count reaches a value of 8, the UART RXD value is updated to reflect the value of the decoded data. When the count reaches 12 baud clock periods, the sampling window for the next incoming pulse opens. The window remains open until the count again reaches 8 (that is, 24 baud clock periods since the previous pulse was detected), giving the Endec a sampling window of minus four

5. When the conversion is complete, the ADC control logic performs the following operations:
   - 11-bit two's-complement result written to {ADCD_H[7:0], ADCD_L[7:5]}.
   - CEN resets to 0 to indicate the conversion is complete.
6. If the ADC remains idle for 160 consecutive system clock cycles, it is automatically powered-down.

Continuous Conversion

When configured for continuous conversion, the ADC continuously performs an analog-to-digital conversion on the selected analog input. Each new data value over-writes the previous value stored in the ADC Data registers. An interrupt is generated after each conversion.

! Caution: *In CONTINUOUS mode, ADC updates are limited by the input signal bandwidth of the ADC and the latency of the ADC and its digital filter. Step changes at the input are not detected at the next output from the ADC. The response of the ADC (in all modes) is limited by the input signal bandwidth and the latency.*

Follow the steps below for setting up the ADC and initiating continuous conversion:

1. Enable the acceptable analog input by configuring the general-purpose I/O pins for alternate function. This action disables the digital input and output driver.
2. Write the ADC Control/Status Register 1 to configure the ADC:
   - Write the REFSELH bit of the pair {REFSELH, REFSELL} to select the internal voltage reference level or to disable the internal reference. The REFSELH bit is contained in the ADC Control/Status Register 1.
3. Write to the ADC Control Register 0 to configure the ADC for continuous conversion. The bit fields in the ADC Control register can be written simultaneously:
   - Write to the ANAIN[3:0] field to select from the available analog input sources (different input pins available depending on the device).
   - Set CONT to 1 to select continuous conversion.
   - If the internal VREF must be output to a pin, set the REFEXT bit to 1. The internal voltage reference must be enabled in this case.
   - Write the REFSELL bit of the pair {REFSELH, REFSELL} to select the internal voltage reference level or to disable the internal reference. The REFSELL bit is contained in ADC Control Register 0.
   - Set CEN to 1 to start the conversions.

ADC Control/Status Register 1

The second ADC Control register contains the voltage reference level selection bit.

Table 73. ADC Control/Status Register 1 (ADCCTL1)

BITS	7	6	5	4	3	2	1	0
FIELD	REFSELH	Reserved						
RESET	1	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
ADDR	F71H							

REFSELH—Voltage Reference Level Select High Bit; in conjunction with the Low bit (REFSELL) in ADC Control Register 0, this determines the level of the internal voltage reference; the following details the effects of {REFSELH, REFSELL}; this reference is independent of the Comparator reference

00= Internal Reference Disabled, reference comes from external pin
01= Internal Reference set to 1.0 V
10= Internal Reference set to 2.0 V (default)

ADC Data High Byte Register

The ADC Data High Byte register contains the upper eight bits of the ADC output. The output is an 11-bit two's complement value. During a single-shot conversion, this value is invalid. Access to the ADC Data High Byte register is read-only. Reading the ADC Data High Byte register latches data in the ADC Low Bits register.

Table 74. ADC Data High Byte Register (ADCD_H)

BITS	7	6	5	4	3	2	1	0
FIELD	ADCDH							
RESET	X	X	X	X	X	X	X	X
R/W	R	R	R	R	R	R	R	R
ADDR	F72H							

ADCDH—ADC Data High Byte
This byte contains the upper eight bits of the ADC output. These bits are not valid during a single-shot conversion. During a continuous conversion, the most recent conversion output is held in this register. These bits are undefined after a Reset.

Figure 20. Flash Memory Arrangement

Flash Information Area

The Flash information area is separate from program memory and is mapped to the address range FE00H to FFFFH. Not all these addresses are accessible. Factory trim values for the analog peripherals are stored here. Factory calibration data for the ADC is also stored here.

Flash Operation Timing Using the Flash Frequency Registers

Before performing either a program or erase operation on Flash memory, you must first configure the Flash Frequency High and Low Byte registers. The Flash Frequency registers allow programming and erasing of the Flash with system clock frequencies ranging from 32 kHz (32768 Hz) through 20 MHz.

The Flash Frequency High and Low Byte registers combine to form a 16-bit value, FFREQ, to control timing for Flash program and erase operations. The 16-bit binary Flash Frequency value must contain the system clock frequency (in kHz). This value is calculated using the following equation:

$$\text{FFREQ[15:0]} = \frac{\text{System Clock Frequency (Hz)}}{1000}$$

Caution: *Flash programming and erasure are not supported for system clock frequencies below 32 kHz (32768 Hz) or above 20 MHz. The Flash Frequency High and Low Byte registers must be loaded with the correct value to ensure operation of Z8 Encore! XP® F0823 Series devices.*

Flash Code Protection Against External Access

The user code contained within the Flash memory can be protected against external access with the On-Chip Debugger. Programming the FRP Flash Option Bit prevents reading of the user code with the On-Chip Debugger. For more information, see Flash Option Bits on page 141 and On-Chip Debugger on page 151.

Flash Code Protection Against Accidental Program and Erasure

Z8 Encore! XP F0823 Series provides several levels of protection against accidental program and erasure of the Flash memory contents. This protection is provided by a combination of the Flash Option bits, the register locking mechanism, the page select redundancy and the sector level protection control of the Flash Controller.

Flash Code Protection Using the Flash Option Bits

The FRP and FWP Flash Option Bits combine to provide three levels of Flash Program Memory protection as listed in Table 78. For more information, see Flash Option Bits on page 141.

Trim Bit Data Register

The Trim Bid Data (TRMDR) register contains the read or write data for access to the trim option bits.

Table 86. Trim Bit Data Register (TRMDR)

BITS	7	6	5	4	3	2	1	0
FIELD	TRMDR - Trim Bit Data							
RESET	0	0	0	0	0	0	0	0
