

#### Welcome to E-XFL.COM

#### What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

#### Applications of "<u>Embedded -</u> <u>Microcontrollers</u>"

#### Details

#### TABLE 1-6: PIC18F96J60/96J65/97J60 PINOUT I/O DESCRIPTIONS (CONTINUED)

Note 1: Alternate assignment for ECCP2/P2A when CCP2MX Configuration bit is cleared (Extended Microcontroller mode).

2: Default assignment for ECCP2/P2A for all devices in all operating modes (CCP2MX Configuration bit is set).

3: Default assignments for P1B/P1C/P3B/P3C (ECCPMX Configuration bit is set).

4: Alternate assignment for ECCP2/P2A when CCP2MX Configuration bit is cleared (Microcontroller mode).

5: Alternate assignments for P1B/P1C/P3B/P3C (ECCPMX Configuration bit is cleared).

#### 3.7.1 OSCILLATOR CONTROL REGISTER

The OSCCON register (Register 3-2) controls several aspects of the device clock's operation, both in full-power operation and in power-managed modes.

The System Clock Select bits, SCS<1:0>, select the clock source. The available clock sources are the primary clock (defined by the FOSC<2:0> Configuration bits), the secondary clock (Timer1 oscillator) and the internal oscillator. The clock source changes after one or more of the bits are changed, following a brief clock transition interval.

The OSTS (OSCCON<3>) and T1RUN (T1CON<6>) bits indicate which clock source is currently providing the device clock. The T1RUN bit indicates when the Timer1 oscillator is providing the device clock in secondary clock modes. In power-managed modes, only one of these bits will be set at any time. If neither bit is set, the INTRC source is providing the clock, or the internal oscillator has just started and is not yet stable.

The IDLEN bit determines if the device goes into Sleep mode or one of the Idle modes when the SLEEP instruction is executed.

The use of the flag and control bits in the OSCCON register is discussed in more detail in **Section 4.0** "**Power-Managed Modes**".

- Note 1: The Timer1 oscillator must be enabled to select the secondary clock source. The Timer1 oscillator is enabled by setting the T1OSCEN bit in the Timer1 Control register (T1CON<3>). If the Timer1 oscillator is not enabled, then any attempt to select a secondary clock source will be ignored.
  - 2: It is recommended that the Timer1 oscillator be operating and stable before executing the SLEEP instruction or a very long delay may occur while the Timer1 oscillator starts.

#### 8.6.3 16-BIT BYTE SELECT MODE

Figure 8-3 shows an example of 16-Bit Byte Select mode. This mode allows table write operations to word-wide external memories with byte selection capability. This generally includes both word-wide Flash and SRAM devices.

During a TBLWT cycle, the TABLAT data is presented on the upper and lower byte of the AD<15:0> bus. The WRH signal is strobed for each write cycle; the WRL pin is not used. The BA0 or UB/LB signals are used to select the byte to be written based on the Least Significant bit of the TBLPTR register. Flash and SRAM devices use different control signal combinations to implement Byte Select mode. JEDEC standard Flash memories require that a controller I/O port pin be connected to the memory's BYTE/WORD pin to provide the select signal. They also use the BA0 signal from the controller as a byte address. JEDEC standard, static RAM memories, on the other hand, use the UB or LB signals to select the byte.

#### **19.3 Ethernet Interrupts**

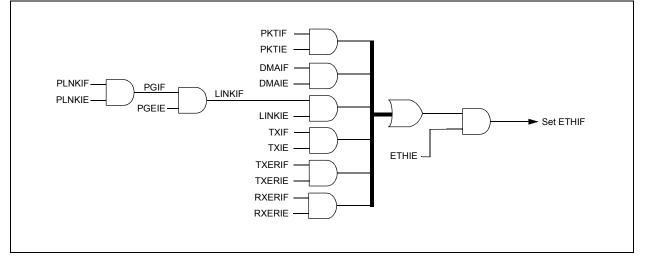

The Ethernet module can generate multiple interrupt conditions. To accommodate all of these sources, the module has its own interrupt logic structure, similar to that of the microcontroller. Separate sets of registers are used to enable and flag different interrupt conditions.

The EIE register contains the individual interrupt enable bits for each source, while the EIR register contains the corresponding interrupt flag bits. When an interrupt occurs, the interrupt flag is set. If the interrupt is enabled in the EIE register, and the corresponding ETHIE Global Interrupt Enable bit is set, the microcontroller's master Ethernet Interrupt Flag (ETHIF) is set, as appropriate (see Figure 19-7). Note: Except for the LINKIF interrupt flag, interrupt flag bits are set when an interrupt condition occurs, regardless of the state of its corresponding enable bit or the associated global enable bit. User software should ensure the appropriate interrupt flag bits are clear prior to enabling an interrupt. This feature allows for software polling.

#### 19.3.1 CONTROL INTERRUPT (ETHIE)

The four registers associated with the control interrupts are shown in Register 19-14 through Register 19-17.

2: If the I<sup>2</sup>C module is active, these bits may not be set (no spooling) and the SSPxBUF may not be written (or writes to the SSPxBUF are disabled).

#### 20.4.3.3 Reception

When the R/W bit of the address byte is clear and an address match occurs, the R/W bit of the SSPxSTAT register is cleared. The received address is loaded into the SSPxBUF register and the SDAx line is held low (ACK).

When the address byte overflow condition exists, then the no Acknowledge (ACK) pulse is given. An overflow condition is defined as either bit, BF (SSPxSTAT<0>), is set, or bit, SSPOV (SSPxCON1<6>), is set.

An MSSP interrupt is generated for each data transfer byte. The interrupt flag bit, SSPxIF, must be cleared in software. The SSPxSTAT register is used to determine the status of the byte.

If SEN is enabled (SSPxCON2<0> = 1), SCKx/SCLx (RC3 or RD6) will be held low (clock stretch) following each data transfer. The clock must be released by setting bit, CKP (SSPxCON1<4>). See **Section 20.4.4** "**Clock Stretching**" for more details.

#### 20.4.3.4 Transmission

When the R/W bit of the incoming address byte is set and an address match occurs, the R/W bit of the SSPxSTAT register is set. The received address is loaded into the SSPxBUF register. The ACK pulse will be sent on the ninth bit and pin RC3 or RD6 is held low, regardless of SEN (see **Section 20.4.4** "**Clock Stretching**" for more details). By stretching the clock, the master will be unable to assert another clock pulse until the slave is done preparing the transmit data. The transmit data must be loaded into the SSPxBUF register which also loads the SSPxSR register. Then, pin, RC3 or RD6, should be enabled by setting bit, CKP (SSPxCON1<4>). The eight data bits are shifted out on the falling edge of the SCLx input. This ensures that the SDAx signal is valid during the SCLx high time (Figure 20-10).

The ACK pulse from the master-receiver is latched on the rising edge of the ninth SCLx input pulse. If the SDAx line is high (not ACK), then the data transfer is complete. In this case, when the ACK is latched by the slave, the slave logic is reset (resets SSPxSTAT register) and the slave monitors for another occurrence of the Start bit. If the SDAx line was low (ACK), the next transmit data must be loaded into the SSPxBUF register. Again, pin, RC3 or RD6, must be enabled by setting bit, CKP.

An MSSP interrupt is generated for each data transfer byte. The SSPxIF bit must be cleared in software and the SSPxSTAT register is used to determine the status of the byte. The SSPxIF bit is set on the falling edge of the ninth clock pulse.

### 20.4.17.1 Bus Collision During a Start Condition

During a Start condition, a bus collision occurs if:

- a) SDAx or SCLx are sampled low at the beginning of the Start condition (Figure 20-28).
- b) SCLx is sampled low before SDAx is asserted low (Figure 20-29).

During a Start condition, both the SDAx and the SCLx pins are monitored.

If the SDAx pin is already low, or the SCLx pin is already low, then all of the following occur:

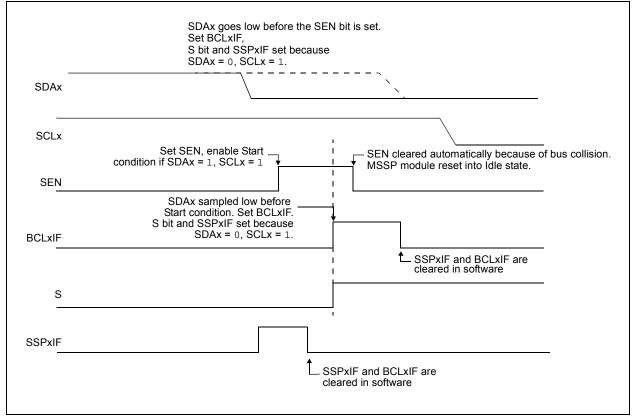

- · the Start condition is aborted;
- · the BCLxIF flag is set; and
- the MSSP module is reset to its Idle state (Figure 20-28).

The Start condition begins with the SDAx and SCLx pins deasserted. When the SDAx pin is sampled high, the Baud Rate Generator is loaded from SSPxADD<6:0> and counts down to 0. If the SCLx pin is sampled low while SDAx is high, a bus collision occurs, because it is assumed that another master is attempting to drive a data '1' during the Start condition.

If the SDAx pin is sampled low during this count, the BRG is reset and the SDAx line is asserted early (Figure 20-30). If, however, a '1' is sampled on the SDAx pin, the SDAx pin is asserted low at the end of the BRG count. The Baud Rate Generator is then reloaded and counts down to 0. If the SCLx pin is sampled as '0' during this time, a bus collision does not occur. At the end of the BRG count, the SCLx pin is asserted low.

Note: The reason that bus collision is not a factor during a Start condition is that no two bus masters can assert a Start condition at the exact same time. Therefore, one master will always assert SDAx before the other. This condition does not cause a bus collision because the two masters must be allowed to arbitrate the first address following the Start condition. If the address is the same, arbitration must be allowed to continue into the data portion, Repeated Start or Stop conditions.

#### TABLE 26-1: OPCODE FIELD DESCRIPTIONS

| Field           | Description                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| a               | RAM access bit:                                                                                                                             |
|                 | a = 0: RAM location in Access RAM (BSR register is ignored)                                                                                 |
|                 | a = 1: RAM bank is specified by BSR register                                                                                                |
| bbb             | Bit address within an 8-bit file register (0 to 7).                                                                                         |
| BSR             | Bank Select Register. Used to select the current RAM bank.                                                                                  |
| C, DC, Z, OV, N | ALU Status bits: Carry, Digit Carry, Zero, Overflow, Negative.                                                                              |
| d               | Destination select bit:                                                                                                                     |
|                 | d = 0: store result in WREG                                                                                                                 |
| -               | d = 1: store result in file register f                                                                                                      |
| dest            | Destination: either the WREG register or the specified register file location.                                                              |
| f               | 8-bit Register file address (00h to FFh), or 2-bit FSR designator (0h to 3h).                                                               |
| fs              | 12-bit Register file address (000h to FFFh). This is the source address.                                                                    |
| f <sub>d</sub>  | 12-bit Register file address (000h to FFFh). This is the destination address.                                                               |
| GIE             | Global Interrupt Enable bit.                                                                                                                |
| k               | Literal field, constant data or label (may be either an 8-bit, 12-bit or a 20-bit value).                                                   |
| label           | Label name.                                                                                                                                 |
| mm              | The mode of the TBLPTR register for the table read and table write instructions.<br>Only used with table read and table write instructions: |
| *               | No Change to register (such as TBLPTR with table reads and writes)                                                                          |
| *+              | Post-Increment register (such as TBLPTR with table reads and writes)                                                                        |
| *_              | Post-Decrement register (such as TBLPTR with table reads and writes)                                                                        |
| +*              | Pre-Increment register (such as TBLPTR with table reads and writes)                                                                         |
|                 | The relative address (2's complement number) for relative branch instructions or the direct address for                                     |
| n               | Call/Branch and Return instructions.                                                                                                        |
| PC              | Program Counter.                                                                                                                            |
| PCL             | Program Counter Low Byte.                                                                                                                   |
| PCH             | Program Counter High Byte.                                                                                                                  |
| PCLATH          | Program Counter High Byte Latch.                                                                                                            |
| PCLATU          | Program Counter Upper Byte Latch.                                                                                                           |
| PD              | Power-Down bit.                                                                                                                             |
| PRODH           | Product of Multiply High Byte.                                                                                                              |
| PRODL           | Product of Multiply Low Byte.                                                                                                               |
| s               | Fast Call/Return mode select bit:                                                                                                           |
| 5               | s = 0: do not update into/from shadow registers                                                                                             |
|                 | s = 1: certain registers loaded into/from shadow registers (Fast mode)                                                                      |
| TBLPTR          | 21-bit Table Pointer (points to a program memory location).                                                                                 |
| TABLAT          | 8-bit Table Latch.                                                                                                                          |
| TO              | Time-out bit.                                                                                                                               |
| TOS             | Top-of-Stack.                                                                                                                               |
| u               | Unused or Unchanged.                                                                                                                        |
| WDT             | Watchdog Timer.                                                                                                                             |
| WREG            | Working register (accumulator).                                                                                                             |
| х               | Don't care ('0' or '1'). The assembler will generate code with $x = 0$ . It is the recommended form of use for                              |
|                 | compatibility with all Microchip software tools.                                                                                            |
| Zs              | 7-bit offset value for indirect addressing of register files (source).                                                                      |
| zd              | 7-bit offset value for indirect addressing of register files (destination).                                                                 |
| { }             | Optional argument.                                                                                                                          |
| [text]          | Indicates an indexed address.                                                                                                               |
| (text)          | The contents of text.                                                                                                                       |
| [expr] <n></n>  | Specifies bit n of the register indicated by the pointer expr.                                                                              |

#### 26.2.3 BYTE-ORIENTED AND BIT-ORIENTED INSTRUCTIONS IN INDEXED LITERAL OFFSET MODE

| Note: | Enabling the PIC18 instruction set exten- |  |  |  |  |  |  |  |
|-------|-------------------------------------------|--|--|--|--|--|--|--|
|       | sion may cause legacy applications to     |  |  |  |  |  |  |  |
|       | behave erratically or fail entirely.      |  |  |  |  |  |  |  |

In addition to eight new commands in the extended set, enabling the extended instruction set also enables Indexed Literal Offset Addressing (Section 6.6.1 "Indexed Addressing with Literal Offset"). This has a significant impact on the way that many commands of the standard PIC18 instruction set are interpreted.

When the extended set is disabled, addresses embedded in opcodes are treated as literal memory locations: either as a location in the Access Bank (a = 0) or in a GPR bank designated by the BSR (a = 1). When the extended instruction set is enabled and a = 0, however, a file register argument of 5Fh or less is interpreted as an offset from the pointer value in FSR2 and not as a literal address. For practical purposes, this means that all instructions that use the Access RAM bit as an argument – that is, all byte-oriented and bit-oriented instructions, or almost half of the core PIC18 instructions – may behave differently when the extended instruction set is enabled.

When the content of FSR2 is 00h, the boundaries of the Access RAM are essentially remapped to their original values. This may be useful in creating backward-compatible code. If this technique is used, it may be necessary to save the value of FSR2 and restore it when moving back and forth between C and assembly routines in order to preserve the Stack Pointer. Users must also keep in mind the syntax requirements of the extended instruction set (see Section 26.2.3.1 "Extended Instruction Syntax with Standard PIC18 Commands").

Although the Indexed Literal Offset mode can be very useful for dynamic stack and pointer manipulation, it can also be very annoying if a simple arithmetic operation is carried out on the wrong register. Users who are accustomed to the PIC18 programming must keep in mind that, when the extended instruction set is enabled, register addresses of 5Fh or less are used for Indexed Literal Offset Addressing.

Representative examples of typical byte-oriented and bit-oriented instructions in the Indexed Literal Offset mode are provided on the following page to show how execution is affected. The operand conditions shown in the examples are applicable to all instructions of these types.

### 26.2.3.1 Extended Instruction Syntax with Standard PIC18 Commands

When the extended instruction set is enabled, the file register argument 'f' in the standard byte-oriented and bit-oriented commands is replaced with the literal offset value 'k'. As already noted, this occurs only when 'f' is less than or equal to 5Fh. When an offset value is used, it must be indicated by square brackets ("[]"). As with the extended instructions, the use of brackets indicates to the compiler that the value is to be interpreted as an index or an offset. Omitting the brackets, or using a value greater than 5Fh within the brackets, will generate an error in the MPASM Assembler.

If the index argument is properly bracketed for Indexed Literal Offset Addressing, the Access RAM argument is never specified; it will automatically be assumed to be '0'. This is in contrast to standard operation (extended instruction set disabled), when 'a' is set on the basis of the target address. Declaring the Access RAM bit in this mode will also generate an error in the MPASM Assembler.

The destination argument 'd' functions as before.

In the latest versions of the MPASM Assembler, language support for the extended instruction set must be explicitly invoked. This is done with either the command line option,  $/_{Y}$ , or the PE directive in the source listing.

#### 26.2.4 CONSIDERATIONS WHEN ENABLING THE EXTENDED INSTRUCTION SET

It is important to note that the extensions to the instruction set may not be beneficial to all users. In particular, users who are not writing code that uses a software stack may not benefit from using the extensions to the instruction set.

Additionally, the Indexed Literal Offset Addressing mode may create issues with legacy applications written to the PIC18 assembler. This is because instructions in the legacy code may attempt to address registers in the Access Bank below 5Fh. Since these addresses are interpreted as literal offsets to FSR2 when the instruction set extension is enabled, the application may read or write to the wrong data addresses.

When porting an application to the PIC18F97J60 family, it is very important to consider the type of code. A large, reentrant application that is written in C and would benefit from efficient compilation will do well when using the instruction set extensions. Legacy applications that heavily use the Access Bank will most likely not benefit from using the extended instruction set.

### 28.0 ELECTRICAL CHARACTERISTICS

### Absolute Maximum Ratings<sup>(†)</sup>

| Ambient temperature under bias                                                       | 40°C to +100°C        |
|--------------------------------------------------------------------------------------|-----------------------|
| Storage temperature                                                                  | 65°C to +150°C        |
| Voltage on any digital only input pin or MCLR with respect to Vss (except VDD)       | 0.3V to 6.0V          |

| Voltage on VDDCORE with respect to Vss                                               | 0.3V to 2.75V         |
| Voltage on VDD with respect to Vss                                                   | -0.3V to 4.0V         |
| Total power dissipation (Note 1)                                                     | 1.0W                  |
| Maximum current out of Vss pin                                                       | 300 mA                |
| Maximum current into VDD pin                                                         | 250 mA                |
| Input clamp current, Iικ (Vι < 0 or Vι > VDD) (Note 2)                               | ±0 mA                 |
| Output clamp current, Ioκ (Vo < 0 or Vo > VDD) (Note 2)                              | ±0 mA                 |
| Maximum output current sunk by any PORTB and PORTC I/O pins                          | 25 mA                 |
| Maximum output current sunk by any PORTD, PORTE and PORTJ I/O pins                   | 8 mA                  |
| Maximum output current sunk by any PORTA, PORTF, PORTG and PORTH I/O pins (Note 3)   | 2 mA                  |
| Maximum output current sourced by any PORTB and PORTC I/O pins                       | 25 mA                 |
| Maximum output current sourced by any PORTD, PORTE and PORTJ I/O pins                | 8 mA                  |
| Maximum output current sourced by any PORTA, PORTF, PORTG and PORTH I/O pins (Note 3 | <b>3)</b> 2 mA        |
| Maximum current sunk by all ports combined                                           | 200 mA                |
| Maximum current sourced by all ports combined                                        | 200 mA                |

Note 1: Power dissipation is calculated as follows:

Pdis = VDD x {IDD  $-\Sigma$  IOH} +  $\Sigma$  {(VDD - VOH) x IOH} +  $\Sigma$  (VOL x IOL) +  $\Sigma$  (VTPOUT x ITPOUT)

- 2: No clamping diodes are present.
- 3: Exceptions are RA<1> and RA<0>, which are capable of directly driving LEDs up to 25 mA.

**† NOTICE:** Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

**Note 1:** Negative current is defined as current sourced by the pin.

#### 29.2 Package Details

The following sections give the technical details of the packages.

#### 64-Lead Plastic Thin Quad Flatpack (PT) – 10x10x1 mm Body, 2.00 mm [TQFP]

**Note:** For the most current package drawings, please see the Microchip Packaging Specification located at http://www.microchip.com/packaging

#### Notes:

- 1. Pin 1 visual index feature may vary, but must be located within the hatched area.
- 2. Chamfers at corners are optional; size may vary.

Mold Draft Angle Bottom

3. Dimensions D1 and E1 do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.25 mm per side.

β

11°

12°

- 4. Dimensioning and tolerancing per ASME Y14.5M.
  - BSC: Basic Dimension. Theoretically exact value shown without tolerances.

REF: Reference Dimension, usually without tolerance, for information purposes only.
