

Welcome to [E-XFL.COM](https://www.e-xfl.com)

What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "[Embedded - Microcontrollers](#)"

Details

Product Status	Not For New Designs
Core Processor	V850ES
Core Size	32-Bit Single-Core
Speed	32MHz
Connectivity	CSI, EBI/EMI, I ² C, UART/USART
Peripherals	DMA, LVD, PWM, WDT
Number of I/O	84
Program Memory Size	1MB (1M x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	60K x 8
Voltage - Supply (Vcc/Vdd)	2.85V ~ 3.6V
Data Converters	A/D 12x10b; D/A 2x8b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	100-LQFP
Supplier Device Package	-
Purchase URL	https://www.e-xfl.com/product-detail/renesas-electronics-america/upd70f3742gc-ueu-ax

(3) System status register (SYS)

Status flags that indicate the operation status of the overall system are allocated to this register.

This register can be read or written in 8-bit or 1-bit units.

Reset sets this register to 00H.

After reset: 00H		R/W	Address: FFFFF802H					
SYS	7	6	5	4	3	2	1	<0>
	0	0	0	0	0	0	0	PRERR
PRERR		Detects protection error						
0		Protection error did not occur						
1		Protection error occurred						

The PRERR flag operates under the following conditions.

(a) Set condition (PRERR flag = 1)

- (i) When data is written to a special register without writing anything to the PRCMD register (when <4> is executed without executing <3> in **3.4.7 (1) Setting data to special registers**)
- (ii) When data is written to an on-chip peripheral I/O register other than a special register (including execution of a bit manipulation instruction) after writing data to the PRCMD register (if <4> in **3.4.7 (1) Setting data to special registers** is not the setting of a special register)

Remark Even if an on-chip peripheral I/O register is read (except by a bit manipulation instruction) between an operation to write the PRCMD register and an operation to write a special register, the PRERR flag is not set, and the set data can be written to the special register.

(b) Clear condition (PRERR flag = 0)

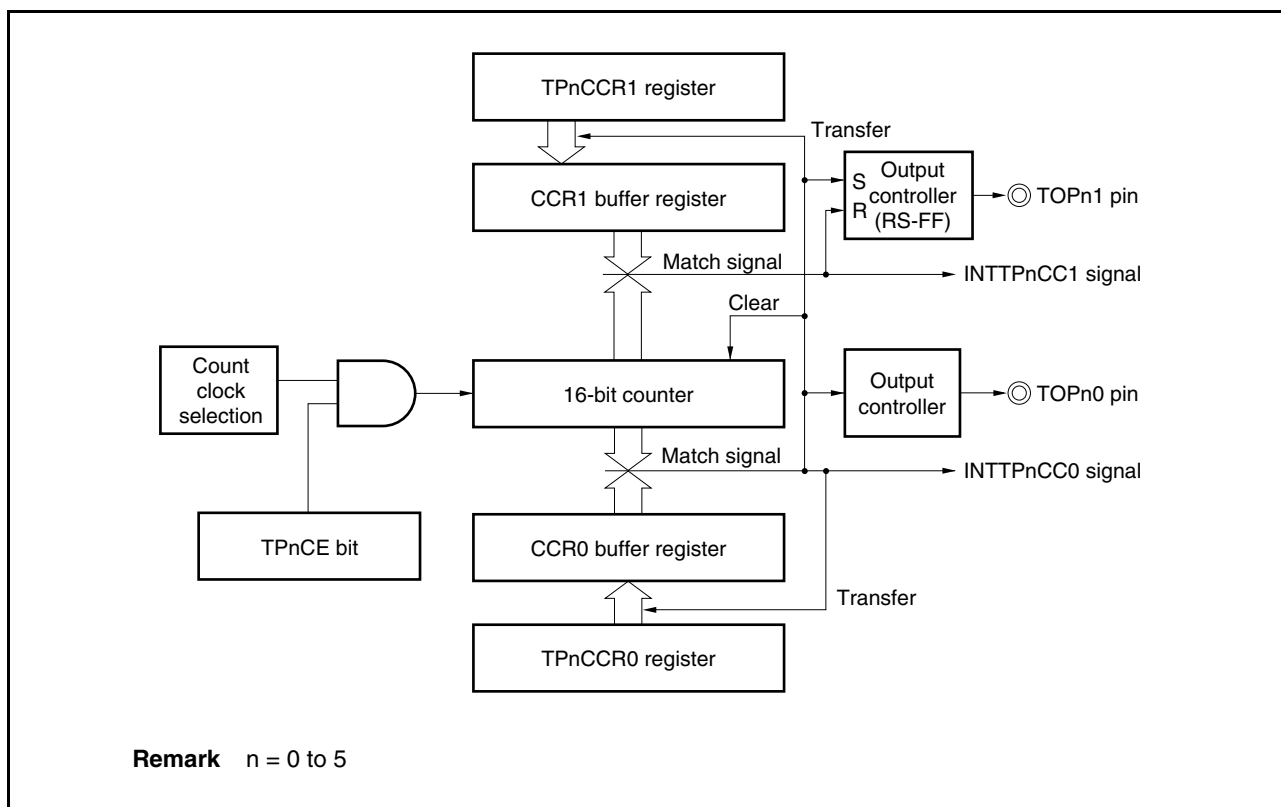

- (i) When 0 is written to the PRERR flag
- (ii) When the system is reset

- Cautions**
1. If 0 is written to the PRERR bit of the SYS register, which is not a special register, immediately after a write access to the PRCMD register, the PRERR bit is cleared to 0 (the write access takes precedence).
 2. If data is written to the PRCMD register, which is not a special register, immediately after a write access to the PRCMD register, the PRERR bit is set to 1.

7.5.5 PWM output mode (TPnMD2 to TPnMD0 bits = 100)

In the PWM output mode, a PWM waveform is output from the TOPn1 pin when the TPnCTL0.TPnCE bit is set to 1. In addition, a pulse with one cycle of the PWM waveform as half its cycle is output from the TOPn0 pin.

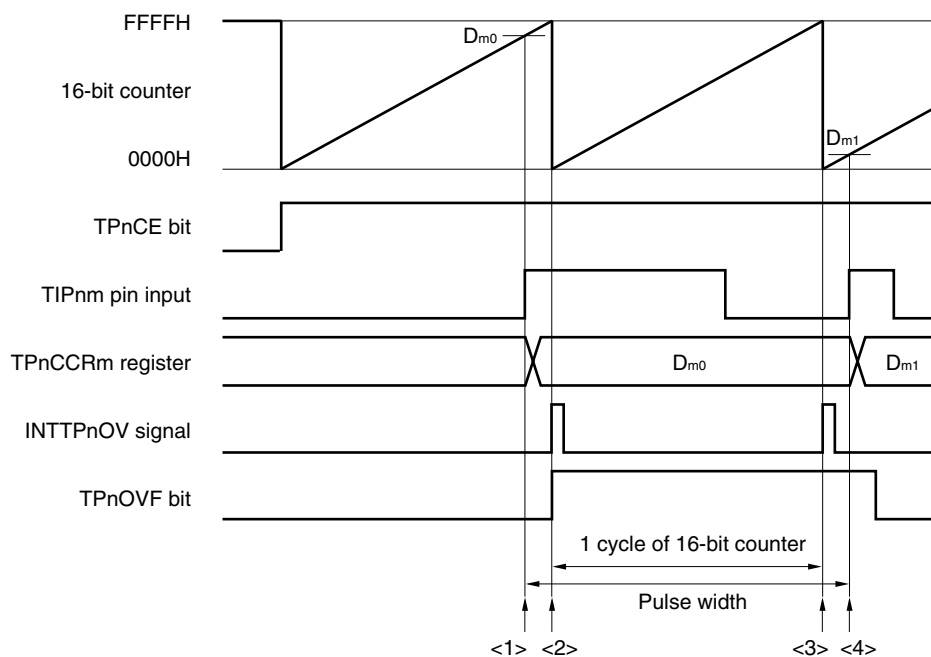

Figure 7-24. Configuration in PWM Output Mode

(d) Processing of overflow if capture trigger interval is long

If the pulse width is greater than one cycle of the 16-bit counter, care must be exercised because an overflow may occur more than once from the first capture trigger to the next. First, an example of incorrect processing is shown below.

Example of incorrect processing when capture trigger interval is long

The following problem may occur when long pulse width is measured in the free-running timer mode.

- <1> Read the TPnCCRM register (setting of the default value of the TIPnm pin input).
- <2> An overflow occurs. Nothing is done by software.
- <3> An overflow occurs a second time. Nothing is done by software.
- <4> Read the TPnCCRM register.
 Read the overflow flag. If the overflow flag is 1, clear it to 0.
 Because the overflow flag is 1, the pulse width can be calculated by $(10000H + D_{m1} - D_{m0})$ (incorrect).
 Actually, the pulse width must be $(20000H + D_{m1} - D_{m0})$ because an overflow occurs twice.

If an overflow occurs twice or more when the capture trigger interval is long, the correct pulse width may not be obtained.

If the capture trigger interval is long, slow the count clock to lengthen one cycle of the 16-bit counter, or use software. An example of how to use software is shown next.

(6) TMQ0 option register 0 (TQ0OPT0)

The TQ0OPT0 register is an 8-bit register used to set the capture/compare operation and detect an overflow.

This register can be read or written in 8-bit or 1-bit units.

Reset sets this register to 00H.

After reset: 00H R/W Address: FFFFF545H

	7	6	5	4	3	2	1	<0>
TQ0OPT0	TQ0CCS3	TQ0CCS2	TQ0CCS1	TQ0CCS0	0	0	0	TQ0OVF

TQ0CCSm	TQ0CCRm register capture/compare selection
0	Compare register selected
1	Capture register selected
The TQ0CCSm bit setting is valid only in the free-running timer mode.	

TQ0OVF	TMQ0 overflow detection
Set (1)	Overflow occurred
Reset (0)	TQ0OVF bit 0 written or TQ0CTL0.TQ0CE bit = 0
<ul style="list-style-type: none"> The TQ0OVF bit is set when the 16-bit counter count value overflows from FFFFH to 0000H in the free-running timer mode or the pulse width measurement mode. An interrupt request signal (INTTQ0OV) is generated at the same time that the TQ0OVF bit is set to 1. The INTTQ0OV signal is not generated in modes other than the free-running timer mode and the pulse width measurement mode. The TQ0OVF bit is not cleared even when the TQ0OVF bit or the TQ0OPT0 register are read when the TQ0OVF bit = 1. The TQ0OVF bit can be both read and written, but the TQ0OVF bit cannot be set to 1 by software. Writing 1 has no influence on the operation of TMQ0. 	

Cautions

1. Rewrite the TQ0CCS3 to TQ0CCS0 bits when the TQ0CTL0.TQ0CE bit = 0. (The same value can be written when the TQ0CE bit = 1.) If rewriting was mistakenly performed, clear the TQ0CE bit to 0 and then set the bits again.

2. Be sure to clear bits 1 to 3 to "0".

Remark m = 0 to 3

pin. If the trigger is generated again while the counter is operating, the counter is cleared to 0000H and restarted. (The output of the TOQ00 pin is inverted. The TOQ0k pin outputs a high-level regardless of the status (high/low) when a trigger is generated.)

The active level width, cycle, and duty factor of the PWM waveform can be calculated as follows.

Active level width = (Set value of TQ0CCRk register) × Count clock cycle

Cycle = (Set value of TQ0CCR0 register + 1) × Count clock cycle

Duty factor = (Set value of TQ0CCRk register)/(Set value of TQ0CCR0 register + 1)

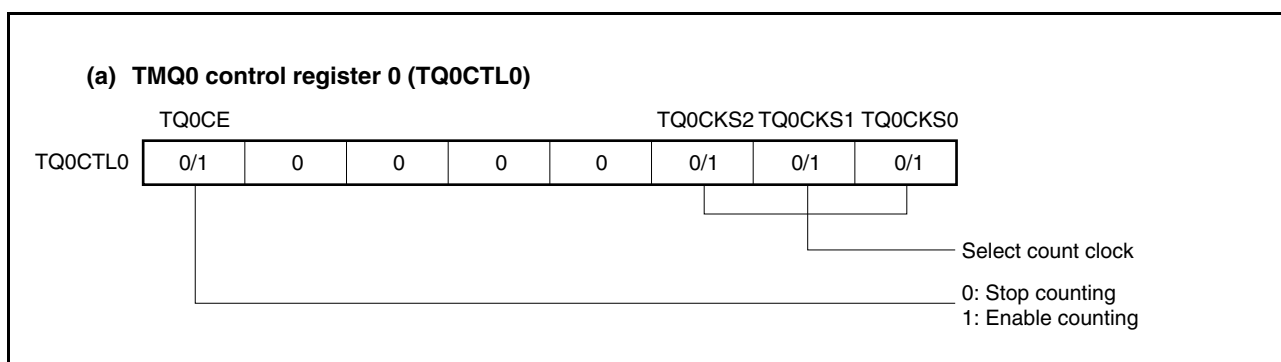

The compare match request signal INTTQ0CC0 is generated when the 16-bit counter counts next time after its count value matches the value of the CCR0 buffer register, and the 16-bit counter is cleared to 0000H. The compare match interrupt request signal INTTQ0CCk is generated when the count value of the 16-bit counter matches the value of the CCRk buffer register.

The value set to the TQ0CCRm register is transferred to the CCRm buffer register when the count value of the 16-bit counter matches the value of the CCR0 buffer register and the 16-bit counter is cleared to 0000H.

The valid edge of an external trigger input signal, or setting the software trigger (TQ0CTL1.TQ0EST bit) to 1 is used as the trigger.

Remark k = 1 to 3, m = 0 to 3

Figure 8-18. Register Setting for Operation in External Trigger Pulse Output Mode (1/3)

(b) When using capture/compare register as capture register

Figure 8-33. Software Processing Flow in Free-Running Timer Mode (Capture Function) (1/2)

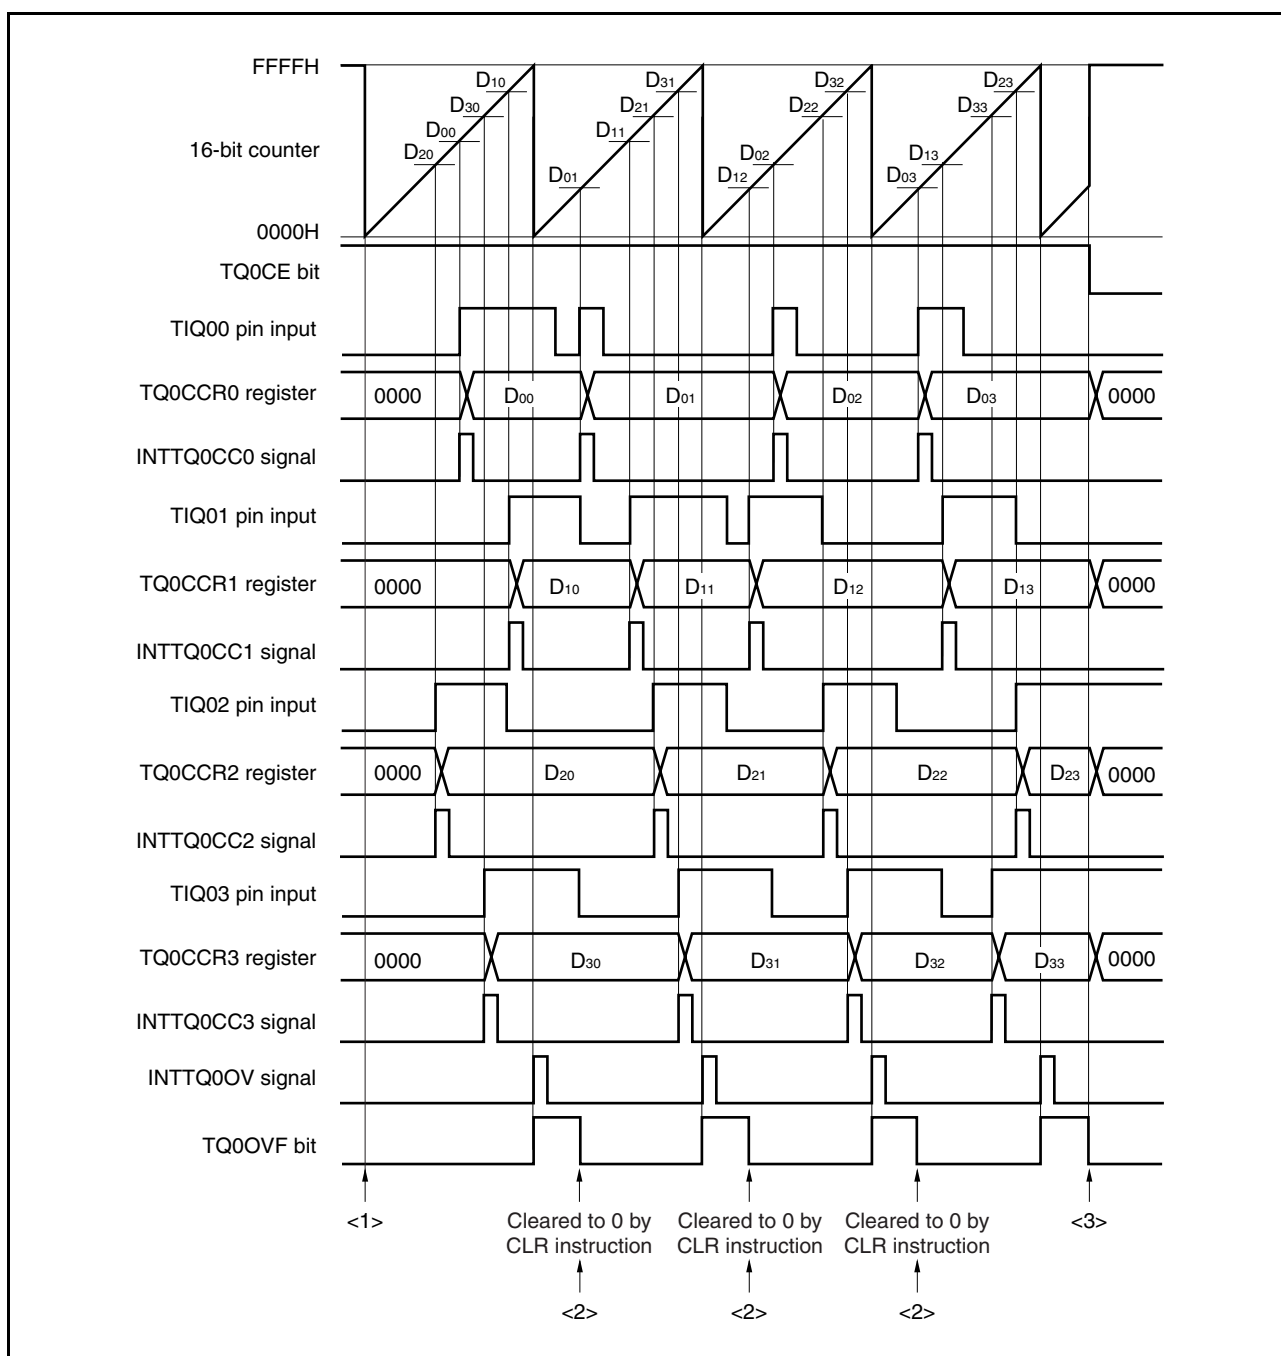

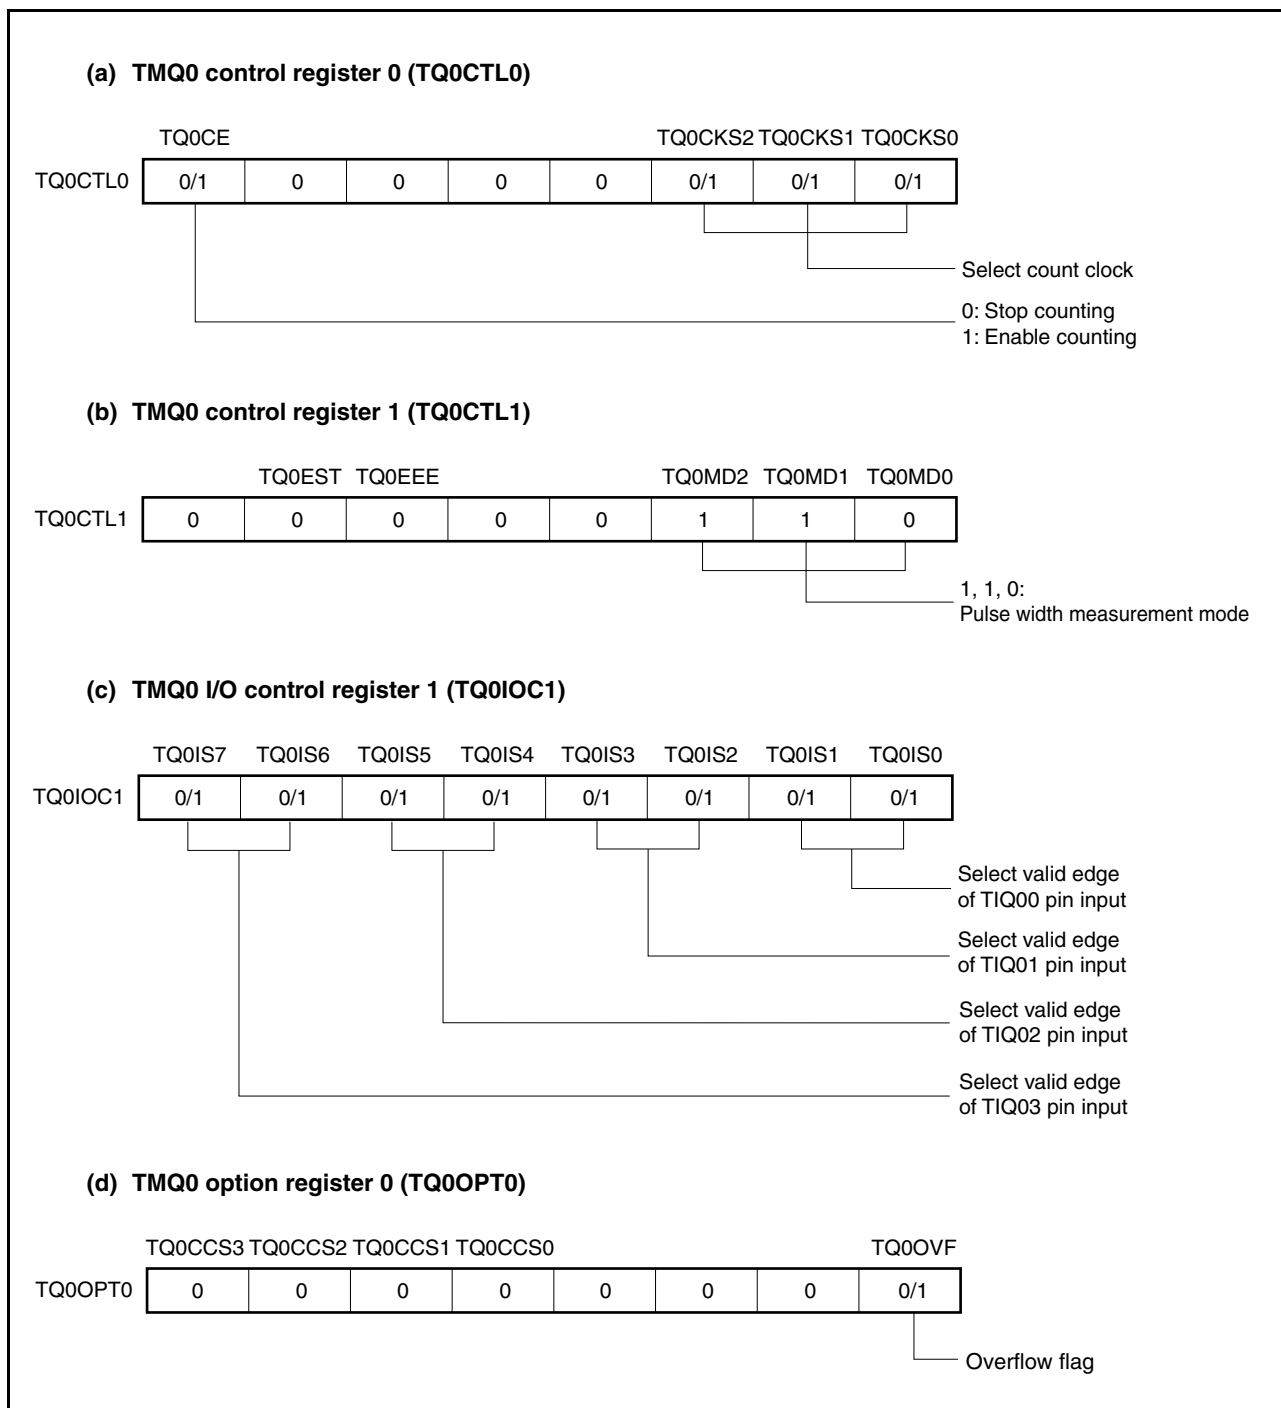

Figure 8-36. Register Setting in Pulse Width Measurement Mode (1/2)

(2) Prescaler compare register 0 (PRSCM0)

The PRSCM0 register is an 8-bit compare register.

This register can be read or written in 8-bit units.

Reset sets this register to 00H.

- Cautions**
1. Do not rewrite the PRSCM0 register during watch timer operation.
 2. Set the PRSCM0 register before setting the PRSM0.BGCE0 bit to 1.
 3. Set the PRSM0 and PRSCM0 registers according to the main clock frequency that is used so as to obtain an f_{BRG} frequency of 32.768 kHz.

The calculation for f_{BRG} is shown below.

$$f_{BRG} = f_{BGCS}/2N$$

Remark f_{BGCS} : Watch timer source clock set by the PRSM0 register

N: Set value of PRSCM0 register = 1 to 256

However, N = 256 only when PRSCM0 register is set to 00H.

11.3 Registers

(1) Watchdog timer mode register 2 (WDTM2)

The WDTM2 register sets the overflow time and operation clock of watchdog timer 2.

This register can be read or written in 8-bit units. This register can be read any number of times, but it can be written only once following reset release.

Reset sets this register to 67H.

Caution Accessing the WDTM2 register is prohibited in the following statuses. For details, see 3.4.8 (2) Accessing specific on-chip peripheral I/O registers.

- When the CPU operates with the subclock and the main clock oscillation is stopped
- When the CPU operates with the internal oscillation clock

After reset: 67H R/W Address: FFFFF6D0H

	7	6	5	4	3	2	1	0
WDTM2	0	WDM21	WDM20	WDCS24	WDCS23	WDCS22	WDCS21	WDCS20

WDM21	WDM20	Selection of operation mode of watchdog timer 2
0	0	Stops operation
0	1	Non-maskable interrupt request mode (generation of INTWDT2 signal)
1	–	Reset mode (generation of WDT2RES signal)

- Cautions**
1. For details of the WDCS20 to WDCS24 bits, see Table 11-2 Watchdog Timer 2 Clock Selection.
 2. Although watchdog timer 2 can be stopped just by stopping the operation of the internal oscillator, clear the WDTM2 register to 00H to securely stop the timer (to avoid selection of the main clock or subclock due to an erroneous write operation).
 3. If the WDTM2 register is rewritten twice after reset, an overflow signal is forcibly generated and the counter is reset.
 4. To intentionally generate an overflow signal, write data to the WDTM2 register only twice, or write a value other than “ACH” to the WDTE register only once.
However, when watchdog timer 2 is set to stop operation, an overflow signal is not generated even if data is written to the WDTM2 register only twice, or a value other than “ACH” is written to the WDTE register only once.
 5. To stop the operation of watchdog timer 2, set the RCM.RSTOP bit to 1 (to stop the internal oscillator) and write 00H in the WDTM2 register. If the RCM.RSTOP bit cannot be set to 1, set the WDCS23 bit to 1 (2ⁿ/f_{xx} is selected and the clock can be stopped in the IDLE1, IDLW2, sub-IDLE, and subclock operation modes).

11.4 Operation

Watchdog timer 2 automatically starts in the reset mode following reset release.

The WDTM2 register can be written to only once following reset using byte access. To use watchdog timer 2, write the operation mode and the interval time to the WDTM2 register using an 8-bit memory manipulation instruction. After this, the operation of watchdog timer 2 cannot be stopped.

The WDCS24 to WDCS20 bits of the WDTM2 register are used to select the watchdog timer 2 loop detection time interval.

Writing ACH to the WDTE register clears the counter of watchdog timer 2 and starts the count operation again. After the count operation has started, write ACH to WDTE within the loop detection time interval.

If the time interval expires without ACH being written to the WDTE register, a reset signal (WDT2RES) or a non-maskable interrupt request signal (INTWDT2) is generated, depending on the set values of the WDM21 and WDTM2.WDM20 bits.

When the WDTM2.WDM21 bit is set to 1 (reset mode), if a WDT overflow occurs during oscillation stabilization after a reset or standby is released, no internal reset will occur and the CPU clock will switch to the internal oscillation clock.

To not use watchdog timer 2, write 00H to the WDTM2 register.

For the non-maskable interrupt servicing while the non-maskable interrupt request mode is set, see **19.2.2 (2) From INTWDT2 signal**.

CHAPTER 12 REAL-TIME OUTPUT FUNCTION (RTO)

12.1 Function

The real-time output function transfers preset data to the RTBL0 and RTBH0 registers, and then transfers this data by hardware to an external device via the output latches, upon occurrence of a timer interrupt. The pins through which the data is output to an external device constitute a port called the real-time output function (RTO).

Because RTO can output signals without jitter, it is suitable for controlling a stepper motor.

In the V850ES/JG3, one 6-bit real-time output port channel is provided.

The real-time output port can be set to the port mode or real-time output port mode in 1-bit units.

13.5 Operation

13.5.1 Basic operation

- <1> Set the operation mode, trigger mode, and conversion time for executing A/D conversion by using the ADA0M0, ADA0M1, ADA0M2, and ADA0S registers. When the ADA0CE bit of the ADA0M0 register is set, conversion is started in the software trigger mode and the A/D converter waits for a trigger in the external or timer trigger mode.
- <2> When A/D conversion is started, the voltage input to the selected analog input channel is sampled by the sample & hold circuit.
- <3> When the sample & hold circuit samples the input channel for a specific time, it enters the hold status, and holds the input analog voltage until A/D conversion is complete.
- <4> Set bit 9 of the successive approximation register (SAR) to set the compare voltage generation DAC to $(1/2) AV_{REF0}$.
- <5> The voltage difference between the voltage of the compare voltage generation DAC and the analog input voltage is compared by the voltage comparator. If the analog input voltage is higher than $(1/2) AV_{REF0}$, the MSB of the SAR register remains set. If it is lower than $(1/2) AV_{REF0}$, the MSB is reset.
- <6> Next, bit 8 of the SAR register is automatically set and the next comparison is started. Depending on the value of bit 9, to which a result has been already set, the compare voltage generation DAC is selected as follows.
 - Bit 9 = 1: $(3/4) AV_{REF0}$
 - Bit 9 = 0: $(1/4) AV_{REF0}$
 This compare voltage and the analog input voltage are compared and, depending on the result, bit 8 is manipulated as follows.
 Analog input voltage \geq Compare voltage: Bit 8 = 1
 Analog input voltage \leq Compare voltage: Bit 8 = 0
- <7> This comparison is continued to bit 0 of the SAR register.
- <8> When comparison of the 10 bits is complete, the valid digital result is stored in the SAR register, which is then transferred to and stored in the ADA0CRn register. After that, an A/D conversion end interrupt request signal (INTAD) is generated.
- <9> In one-shot select mode, conversion is stopped^{Note}. In one-shot scan mode, conversion is stopped after scanning once^{Note}. In continuous select mode, repeat steps <2> to <8> until the ADA0M0.ADA0CE bit is cleared to 0. In continuous scan mode, repeat steps <2> to <8> for each channel.

Note In the external trigger mode, timer trigger mode 0, or timer trigger mode 1, the trigger standby status is entered.

Remark The trigger standby status means the status after the stabilization time has passed.

15.2 Features

- Transfer rate: 300 bps to 625 kbps (using internal system clock of 32 MHz and dedicated baud rate generator)
- Full-duplex communication: Internal UARTAn receive data register (UAnRX)
Internal UARTAn transmit data register (UAnTX)
- 2-pin configuration: TXDAn: Transmit data output pin
RXDAn: Receive data input pin
- Reception error output function
 - Parity error
 - Framing error
 - Overrun error
- Interrupt sources: 2
 - Reception complete interrupt (INTUAnR): This interrupt occurs upon transfer of receive data from the receive shift register to receive data register after serial transfer completion, in the reception enabled status.
 - Transmission enable interrupt (INTUAnT): This interrupt occurs upon transfer of transmit data from the transmit data register to the transmit shift register in the transmission enabled status.
- Character length: 7, 8 bits
- Parity function: Odd, even, 0, none
- Transmission stop bit: 1, 2 bits
- On-chip dedicated baud rate generator
- MSB-/LSB-first transfer selectable
- Transmit/receive data inverted input/output possible
- SBF (Sync Break Field) transmission/reception in the LIN (Local Interconnect Network) communication format possible
 - 13 to 20 bits selectable for SBF transmission
 - Recognition of 11 bits or more possible for SBF reception
 - SBF reception flag provided

Remark n = 0 to 2

15.6.7 UART reception

The reception wait status is set by setting the UAnCTL0.UAnPWR bit to 1 and then setting the UAnCTL0.UAnRXE bit to 1. In the reception wait status, the RXDAn pin is monitored and start bit detection is performed.

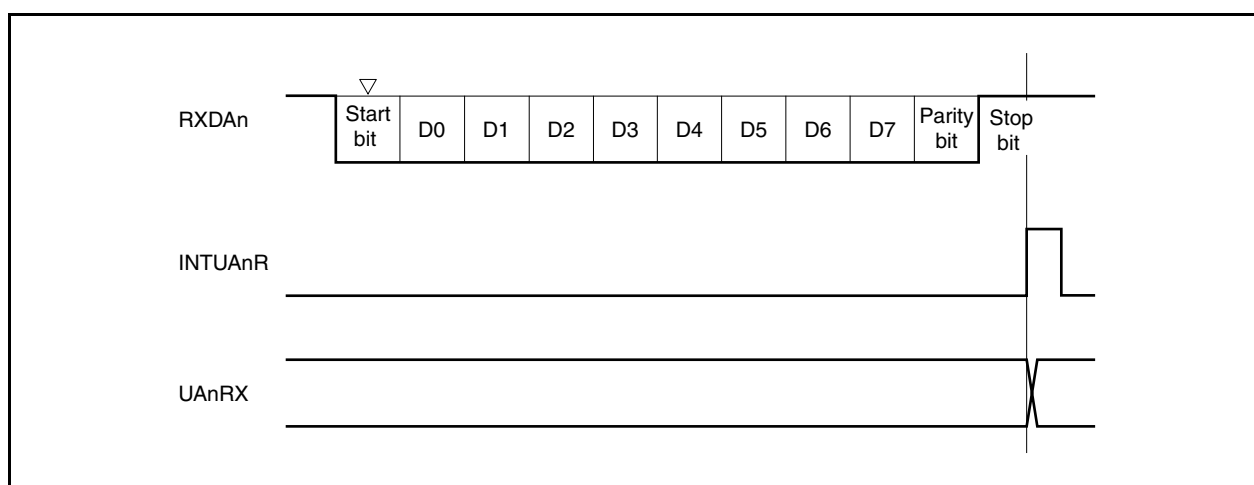

Start bit detection is performed using a two-step detection routine.

First the rising edge of the RXDAn pin is detected and sampling is started at the falling edge. The start bit is recognized if the RXDAn pin is low level at the start bit sampling point. After a start bit has been recognized, the receive operation starts, and serial data is saved to the UARTAn receive shift register according to the set baud rate.

When the reception complete interrupt request signal (INTUAnR) is output upon reception of the stop bit, the data of the UARTAn receive shift register is written to the UAnRX register. However, if an overrun error (UAnSTR.UAnOVE bit) occurs, the receive data at this time is not written to the UAnRX register and is discarded.

Even if a parity error (UAnSTR.UAnPE bit) or a framing error (UAnSTR.UAnFE bit) occurs during reception, reception continues until the reception position of the first stop bit, and INTUAnR is output following reception completion.

Figure 15-13. UART Reception

- Cautions**
1. Be sure to read the UAnRX register even when a reception error occurs. If the UAnRX register is not read, an overrun error occurs during reception of the next data, and reception errors continue occurring indefinitely.
 2. The operation during reception is performed assuming that there is only one stop bit. A second stop bit is ignored.
 3. When reception is completed, read the UAnRX register after the reception complete interrupt request signal (INTUAnR) has been generated, and clear the UAnPWR or UAnRXE bit to 0. If the UAnPWR or UAnRXE bit is cleared to 0 before the INTUAnR signal is generated, the read value of the UAnRX register cannot be guaranteed.
 4. If receive completion processing (INTUAnR signal generation) of UARTAn and the UAnPWR bit = 0 or UAnRXE bit = 0 conflict, the INTUAnR signal may be generated in spite of these being no data stored in the UAnRX register.

To complete reception without waiting INTUAnR signal generation, be sure to clear (0) the interrupt request flag (UAnRIF) of the UAnRIC register, after setting (1) the interrupt mask flag (UAnRMK) of the interrupt control register (UAnRIC) and then set (1) the UAnPWR bit = 0 or UAnRXE bit = 0.

(1) Operation flow

Remarks 1. The broken lines indicate the hardware processing.

2. The numbers in this figure correspond to the processing numbers in (2) **Operation timing**.

3. $n = 0$ to 4

(5) IIC function expansion registers 0 to 2 (IICX0 to IICX2)

The IICXn register sets I²C0n function expansion (valid only in the high-speed mode).

This register can be read or written in 8-bit or 1-bit units.

Setting of the CLXn bit is performed in combination with the SMCn, CLn1, and CLn0 bits of the IICCLn register and the OCKSTHm, OCKSm1, and OCKSm0 bits of the OCKSm register (see **17.4 (6) I²C0n transfer clock setting method**) (m = 0, 1).

Set the IICXn register when the IICCN.IICEn bit = 0.

Reset sets this register to 00H.

After reset: 00H R/W Address: IICX0 FFFFD85H, IICX1 FFFFD95H, IICX2 FFFFDA5H

	7	6	5	4	3	2	1	<0>
IICXn	0	0	0	0	0	0	0	CLXn

(n = 0 to 2)

(6) I²C0n transfer clock setting method

The I²C0n transfer clock frequency (f_{SCL}) is calculated using the following expression (n = 0 to 2).

$$f_{SCL} = 1/(m \times T + t_R + t_F)$$

m = 12, 18, 24, 36, 44, 48, 54, 60, 66, 72, 86, 88, 96, 132, 172, 176, 198, 220, 258, 344 (see **Table 17-2 Clock Settings**).

T: 1/f_{xx}

t_R: SCL0n pin rise time

t_F: SCL0n pin fall time

For example, the I²C0n transfer clock frequency (f_{SCL}) when f_{xx} = 19.2 MHz, m = 198, t_R = 200 ns, and t_F = 50 ns is calculated using following expression.

$$f_{SCL} = 1/(198 \times 52 \text{ ns} + 200 \text{ ns} + 50 \text{ ns}) \cong 94.7 \text{ kHz}$$

The clock to be selected can be set by the combination of the SMCn, CLn1, and CLn0 bits of the IICCLn register, the CLXn bit of the IICXn register, and the OCKSTHm, OCKSm1, and OCKSm0 bits of the OCKSm register (n = 0 to 2, m = 0, 1).

(b) Repeatedly execute setting INITn bit until transfer is forcibly terminated correctly

- <1> Suppress a request from the DMA request source of the channel to be forcibly terminated (stop operation of the on-chip peripheral I/O).
- <2> Check that the DMA transfer request of the channel to be forcibly terminated is not held pending, by using the DTFRn.DFn bit. If a DMA transfer request is held pending, wait until execution of the pending request is completed.
- <3> When it has been confirmed that the DMA request of the channel to be forcibly terminated is not held pending, clear the Enn bit to 0.
- <4> Again, clear the Enn bit of the channel to be forcibly terminated.
If the target of transfer for the channel to be forcibly terminated (transfer source/destination) is the internal RAM, execute this operation once more.
- <5> Copy the initial number of transfers of the channel to be forcibly terminated to a general-purpose register.
- <6> Set the INITn bit of the channel to be forcibly terminated to 1.
- <7> Read the value of the DBCn register of the channel to be forcibly terminated, and compare it with the value copied in <5>. If the two values do not match, repeat operations <6> and <7>.

- Remarks**
1. When the value of the DBCn register is read in <7>, the initial number of transfers is read if forced termination has been correctly completed. If not, the remaining number of transfers is read.
 2. Note that method (b) may take a long time if the application frequently uses DMA transfer for a channel other than the DMA channel to be forcibly terminated.

(5) Procedure of temporarily stopping DMA transfer (clearing Enn bit)

Stop and resume the DMA transfer under execution using the following procedure.

- <1> Suppress a transfer request from the DMA request source (stop the operation of the on-chip peripheral I/O).
- <2> Check the DMA transfer request is not held pending, by using the DFn bit (check if the DFn bit = 0).
If a request is pending, wait until execution of the pending DMA transfer request is completed.
- <3> If it has been confirmed that no DMA transfer request is held pending, clear the Enn bit to 0 (this operation stops DMA transfer).
- <4> Set the Enn bit to 1 to resume DMA transfer.
- <5> Resume the operation of the DMA request source that has been stopped (start the operation of the on-chip peripheral I/O).

(6) Memory boundary

The operation is not guaranteed if the address of the transfer source or destination exceeds the area of the DMA target (external memory, internal RAM, or on-chip peripheral I/O) during DMA transfer.

(7) Transferring misaligned data

DMA transfer of misaligned data with a 16-bit bus width is not supported.

If an odd address is specified as the transfer source or destination, the least significant bit of the address is forcibly assumed to be 0.

Table 28-3. Wiring Between V850ES/JG3 and MINICUBE2

Pin Configuration of MINICUBE2 (QB-MINI2)			With CSIB0-HS		With CSIB3-HS		With UAR0A0

Figure A-2. System Configuration (When Using QB-V850ESSX2) (2/2)

- Notes**
1. Download the device file from the Renesas Electronics website.
<http://www2.renesas.com/micro/ja/ods/index.html>
 2. Under development
 3. Supplied with the device depending on the ordering number.
 - When QB-V850ESSX2-ZZZ is ordered
The exchange adapter and the target connector are not supplied.
 - When QB-V850ESSX2-S100GC is ordered
The QB-100GC-EA-01S and QB-100GC-TC-01S are supplied.
 - When QB-V850ESSX2-T100GC is ordered
The QB-100GC-EA-01T, QB-100GC-YQ-01T, and QB-100GC-NQ-01T are supplied.
 4. When using both <9> and <10>, the order between <9> and <10> is not cared.

<5> QB-V850ESSX2 ^{Note} In-circuit emulator	The in-circuit emulator serves to debug hardware and software when developing application systems using the V850ES/JG3. It supports to the integrated debugger ID850QB. This emulator should be used in combination with a power supply unit and emulation probe. Use the USB interface cable to connect this emulator to the host machine.
<3> USB interface cable	Cable to connect the host machine and the QB-V850ESSX2.
<4> AC adapter	100 to 240 V can be supported by replacing the AC plug.
<8> QB-100GC-EA-01S QB-100GC-EA-01T Exchange adapter	Adapter to perform pin conversion.
<9> QB-100-CA-01S Check pin adapter	Adapter used in waveform monitoring using the oscilloscope, etc.
<10> QB-100-SA-01S QB-100GC-YS-01T Space adapter	Adapter to adjust the height.
<11> QB-100GC-YQ-01T YQ connector	Conversion adapter to connect the target connector and the exchange adapter.
