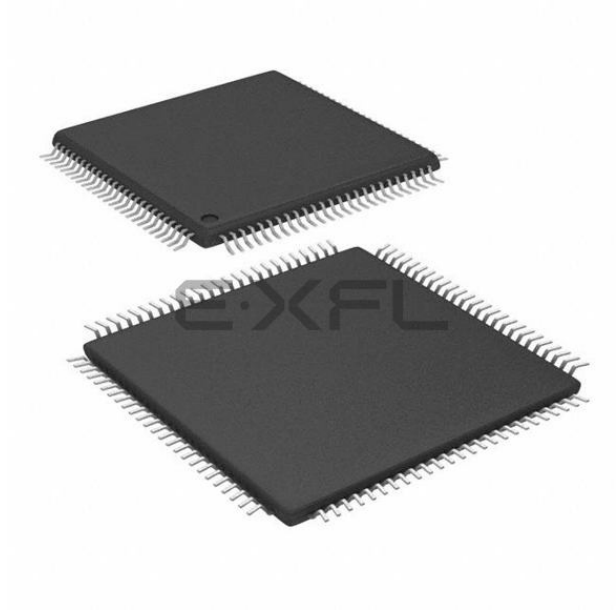
Microchip Technology - PIC24FJ128DA110-I/PT Datasheet



Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	PIC
Core Size	16-Bit
Speed	32MHz
Connectivity	I²C, IrDA, SPI, UART/USART, USB OTG
Peripherals	Brown-out Detect/Reset, GFX, LVD, POR, PWM, WDT
Number of I/O	84
Program Memory Size	128KB (43K x 24)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	24K x 8
Voltage - Supply (Vcc/Vdd)	2.2V ~ 3.6V
Data Converters	A/D 24x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	100-TQFP
Supplier Device Package	100-TQFP (12x12)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic24fj128da110-i-pt

High-Performance CPU

- Modified Harvard Architecture
- Up to 16 MIPS Operation at 32 MHz
- 8 MHz Internal Oscillator
- 17-Bit x 17-Bit Single-Cycle Hardware Multiplier
- 32-Bit by 16-Bit Hardware Divider
- 16 x 16-Bit Working Register Array
- C Compiler Optimized Instruction Set Architecture with Flexible Addressing modes
- Linear Program Memory Addressing, up to 12 Mbytes
- Data Memory Addressing, up to 16 Mbytes:
  - 2K SFR space
  - 30K linear data memory
  - 66K extended data memory
  - Remaining (from 16 Mbytes) memory (external) can be accessed using extended data Memory (EDS) and EPMP (EDS is divided into 32-Kbyte pages)
- Two Address Generation Units for Separate Read and Write Addressing of Data Memory

Power Management:

- On-Chip Voltage Regulator of 1.8V
- Switch between Clock Sources in Real Time
- Idle, Sleep and Doze modes with Fast Wake-up and Two-Speed Start-up
- Run Mode: 800 μA/MIPS, 3.3V Typical
- Sleep mode Current Down to 20 μA, 3.3V Typical
- Standby Current with 32 kHz Oscillator: 22 μA, 3.3V Typical

Analog Features:

- 10-Bit, up to 24-Channel Analog-to-Digital (A/D) Converter at 500 ksps:
  - Operation is possible in Sleep mode
  - Band gap reference input feature
- Three Analog Comparators with Programmable Input/Output Configuration
- Charge Time Measurement Unit (CTMU):
  - Supports capacitive touch sensing for touch screens and capacitive switches
  - Minimum time measurement setting at 100 ps
- Available LVD Interrupt V_{LVD} Level

Special Microcontroller Features:

- Operating Voltage Range of 2.2V to 3.6V
- 5.5V Tolerant Input (digital pins only)
- Configurable Open-Drain Outputs on Digital I/O Ports
- High-Current Sink/Source (18 mA/18 mA) on all I/O Ports
- Selectable Power Management modes:
  - Sleep, Idle and Doze modes with fast wake-up
- Fail-Safe Clock Monitor (FSCM) Operation:
  - Detects clock failure and switches to on-chip, FRC oscillator
- On-Chip LDO Regulator
- Power-on Reset (POR) and Oscillator Start-up Timer (OST)
- Brown-out Reset (BOR)
- Flexible Watchdog Timer (WDT) with On-Chip Low-Power RC Oscillator for Reliable Operation
- In-Circuit Serial Programming™ (ICSP™) and In-Circuit Debug (ICD) via 2 Pins
- JTAG Boundary Scan Support
- Flash Program Memory:
  - 10,000 erase/write cycle endurance (minimum)
  - 20-year data retention minimum
  - Selectable write protection boundary
  - Self-reprogrammable under software control
  - Write protection option for Configuration Words

TABLE 4-6: INTERRUPT CONTROLLER REGISTER MAP (CONTINUED)

Note 1: Bits are unimplemented in 64-pin devices; read as '0'.

EXAMPLE 5-2: ERASING A PROGRAM MEMORY BLOCK ('C' LANGUAGE CODE)

```
// C example using MPLAB C30
    unsigned long progAddr = 0xXXXXXX;          // Address of row to write
    unsigned int offset;
//Set up pointer to the first memory location to be written
    TBLPAG = progAddr>>16;                      // Initialize PM Page Boundary SFR
    offset = progAddr & 0xFFFF;                 // Initialize lower word of address
    __builtin_tblwtl(offset, 0x0000);           // Set base address of erase block
                                                // with dummy latch write
    NVMCON = 0x4042;                            // Initialize NVMCON
    asm("DISI #5");                             // Block all interrupts with priority <7
                                                // for next 5 instructions
    __builtin_write_NVM();                      // check function to perform unlock
                                                // sequence and set WR
```

EXAMPLE 5-3: LOADING THE WRITE BUFFERS

```
; Set up NVMCON for row programming operations
       MOV     #0x4001, W0                      ;
       MOV     W0, NVMCON                       ; Initialize NVMCON
; Set up a pointer to the first program memory location to be written
; program memory selected, and writes enabled
       MOV     #0x0000, W0                      ;
       MOV     W0, TBLPAG                       ; Initialize PM Page Boundary SFR
       MOV     #0x6000, W0                      ; An example program memory address
; Perform the TBLWT instructions to write the latches
; 0th_program_word
       MOV     #LOW_WORD_0, W2                  ;
       MOV     #HIGH_BYTE_0, W3                 ;
       TBLWTL  W2, [W0]                         ; Write PM low word into program latch
       TBLWTH  W3, [W0++]                       ; Write PM high byte into program latch
; 1st_program_word
       MOV     #LOW_WORD_1, W2                  ;
       MOV     #HIGH_BYTE_1, W3                 ;
       TBLWTL  W2, [W0]                         ; Write PM low word into program latch
       TBLWTH  W3, [W0++]                       ; Write PM high byte into program latch
;  2nd_program_word
       MOV     #LOW_WORD_2, W2                  ;
       MOV     #HIGH_BYTE_2, W3                 ;
       TBLWTL  W2, [W0]                         ; Write PM low word into program latch
       TBLWTH  W3, [W0++]                       ; Write PM high byte into program latch
       •
       •
       •
; 63rd_program_word
       MOV     #LOW_WORD_63, W2                 ;
       MOV     #HIGH_BYTE_63, W3                ;
       TBLWTL  W2, [W0]                         ; Write PM low word into program latch
       TBLWTH  W3, [W0]                         ; Write PM high byte into program latch
```

EXAMPLE 5-4: INITIATING A PROGRAMMING SEQUENCE

```
       DISI    #5                       ; Block all interrupts with priority <7
                                        ; for next 5 instructions
       MOV.B   #0x55, W0
       MOV     W0, NVMKEY               ; Write the 0x55 key
       MOV.B   #0xAA, W1                ;
       MOV     W1, NVMKEY               ; Write the 0xAA key
       BSET    NVMCON, #WR              ; Start the programming sequence
       NOP                              ; Required delays
       NOP
       BTSC    NVMCON, #15              ; and wait for it to be
       BRA     $-2                      ; completed
```

TABLE 7-2: IMPLEMENTED INTERRUPT VECTORS

Interrupt Source	Vector Number	IVT Address	AIVT Address	Interrupt Bit Locations		
				Flag	Enable	Priority

Note 1: Not available in 64-pin devices (PIC24FJXXXDAX06).

REGISTER 8-1: OSCCON: OSCILLATOR CONTROL REGISTER (CONTINUED)

bit 10-8 **NOSC<2:0>:** New Oscillator Selection bits(1)
- 111 = Fast RC Oscillator with Postscaler (FRCDIV)
- 110 = Fast RC/16 Oscillator
- 101 = Low-Power RC Oscillator (LPRC)
- 100 = Secondary Oscillator (SOSC)
- 011 = Primary Oscillator with PLL module (XTPLL, HSPLL, ECPLL)
- 010 = Primary Oscillator (XT, HS, EC)
- 001 = Fast RC Oscillator with Postscaler and PLL module (FRCPLL)
- 000 = Fast RC Oscillator (FRC)

bit 7 **CLKLOCK:** Clock Selection Lock Enabled bit

If FSCM is enabled (FCKSM1 = 1):
- 1 = Clock and PLL selections are locked
- 0 = Clock and PLL selections are not locked and may be modified by setting the OSWEN bit

If FSCM is disabled (FCKSM1 = 0):
Clock and PLL selections are never locked and may be modified by setting the OSWEN bit.

bit 6 **IOLOCK:** I/O Lock Enable bit(2)
- 1 = I/O lock is active
- 0 = I/O lock is not active

bit 5 **LOCK:** PLL Lock Status bit(3)
- 1 = PLL module is in lock or PLL module start-up timer is satisfied
- 0 = PLL module is out of lock, PLL start-up timer is running or PLL is disabled

bit 4 **Unimplemented:** Read as '0'

bit 3 **CF:** Clock Fail Detect bit
- 1 = FSCM has detected a clock failure
- 0 = No clock failure has been detected

bit 2 **POSCEN:** Primary Oscillator Sleep Enable bit
- 1 = Primary Oscillator continues to operate during Sleep mode
- 0 = Primary Oscillator is disabled during Sleep mode

bit 1 **SOSCEN:** 32 kHz Secondary Oscillator (SOSC) Enable bit
- 1 = Enable the Secondary Oscillator
- 0 = Disable the Secondary Oscillator

bit 0 **OSWEN:** Oscillator Switch Enable bit
- 1 = Initiate an oscillator switch to the clock source specified by the NOSC<2:0> bits
- 0 = Oscillator switch is complete

Note 1: Reset values for these bits are determined by the FNOSC Configuration bits.

2: The state of the IOLOCK bit can only be changed once an unlocking sequence has been executed. In addition, if the IOL1WAY Configuration bit is '1', once the IOLOCK bit is set, it cannot be cleared.

3: Also resets to '0' during any valid clock switch or whenever a non PLL Clock mode is selected.

Note 1: This register is not available on 64-pin devices (PIC24FJXXXDAX06).

10.4.6 PERIPHERAL PIN SELECT REGISTERS

The PIC24FJ256DA210 family of devices implements a total of 37 registers for remappable peripheral configuration:

- Input Remappable Peripheral Registers (21)
- Output Remappable Peripheral Registers (16)

Note: Input and output register values can only be changed if IOLOCK (OSCCON<6>) = 0. See **Section 10.4.4.1 "Control Register Lock"** for a specific command sequence.

16.0 INTER-INTEGRATED CIRCUIT™ (I^2C™)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the *"PIC24F Family Reference Manual"*, **Section 24. "Inter-Integrated Circuit™ (I^2C™)"** (DS39702). The information in this data sheet supersedes the information in the FRM.

The Inter-Integrated Circuit™ (I^2C™) module is a serial interface useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be serial EEPROMs, display drivers, A/D Converters, etc.

The I^2C module supports these features:

- Independent master and slave logic
- 7-bit and 10-bit device addresses
- General call address, as defined in the I^2C protocol
- Clock stretching to provide delays for the processor to respond to a slave data request
- Both 100 kHz and 400 kHz bus specifications
- Configurable address masking
- Multi-Master modes to prevent loss of messages in arbitration
- Bus Repeater mode, allowing the acceptance of all messages as a slave regardless of the address
- Automatic SCL

A block diagram of the module is shown in Figure 16-1.

16.1 Communicating as a Master in a Single Master Environment

The details of sending a message in Master mode depends on the communications protocol for the device being communicated with. Typically, the sequence of events is as follows:

1. Assert a Start condition on SDAx and SCLx.
2. Send the I^2C device address byte to the slave with a write indication.
3. Wait for and verify an Acknowledge from the slave.
4. Send the first data byte (sometimes known as the command) to the slave.
5. Wait for and verify an Acknowledge from the slave.
6. Send the serial memory address low byte to the slave.
7. Repeat steps 4 and 5 until all data bytes are sent.
8. Assert a Repeated Start condition on SDAx and SCLx.
9. Send the device address byte to the slave with a read indication.
10. Wait for and verify an Acknowledge from the slave.
11. Enable master reception to receive serial memory data.
12. Generate an ACK or NACK condition at the end of a received byte of data.
13. Generate a Stop condition on SDAx and SCLx.

NOTES:

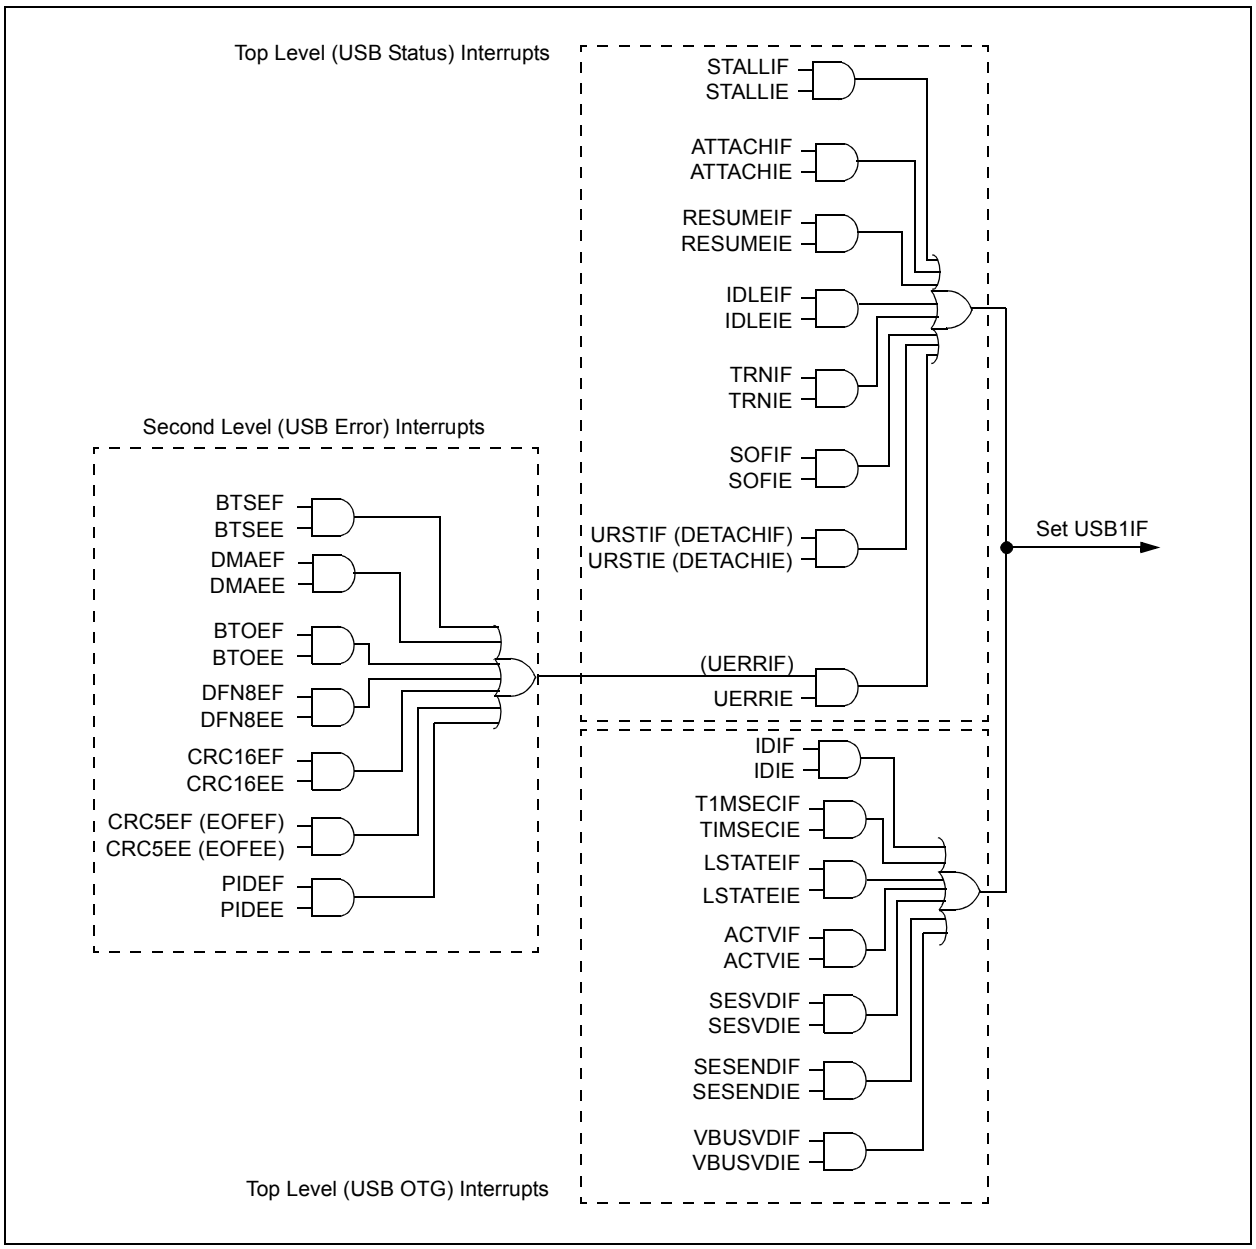
18.3 USB Interrupts

The USB OTG module has many conditions that can be configured to cause an interrupt. All interrupt sources use the same interrupt vector.

Figure 18-9 shows the interrupt logic for the USB module. There are two layers of interrupt registers in the USB module. The top level consists of overall USB status interrupts; these are enabled and flagged in the U1IE and U1IR registers, respectively. The second level consists of USB error conditions, which are enabled and flagged in the U1EIR and U1EIE registers. An interrupt condition in any of these triggers a USB Error Interrupt Flag (UERRIF) in the top level.

Interrupts may be used to trap routine events in a USB transaction. Figure 18-10 provides some common events within a USB frame and their corresponding interrupts.

FIGURE 18-9: USB OTG INTERRUPT FUNNEL



18.5.2 COMPLETE A CONTROL TRANSACTION TO A CONNECTED DEVICE

1. Follow the procedure described in **Section 18.5.1 "Enable Host Mode and Discover a Connected Device"** to discover a device.
2. Set up the Endpoint Control register for bidirectional control transfers by writing 0Dh to U1EP0 (this sets the EPCONDIS, EPTXEN and EPHSHK bits).
3. Place a copy of the device framework setup command in a memory buffer. See *"Chapter 9 of the USB 2.0 Specification"* for information on the device framework command set.
4. Initialize the Buffer Descriptor (BD) for the current (even or odd) TX EP0 to transfer the eight bytes of command data for a device framework command (i.e., `GET DEVICE DESCRIPTOR`):
   a) Set the BD data buffer address (BD0ADR) to the starting address of the 8-byte memory buffer containing the command.
   b) Write 8008h to BD0STAT (this sets the UOWN bit and sets a byte count of 8).
5. Set the USB device address of the target device in the address register (U1ADDR<6:0>). After a USB bus Reset, the device USB address will be zero. After enumeration, it will be set to another value between 1 and 127.
6. Write D0h to U1TOK; this is a SETUP token to Endpoint 0, the target device's default control pipe. This initiates a SETUP token on the bus, followed by a data packet. The device handshake is returned in the PID field of BD0STAT after the packets are complete. When the USB module updates BD0STAT, a transfer done interrupt is asserted (the TRNIF flag is set). This completes the setup phase of the setup transaction as referenced in *"Chapter 9 of the USB Specification"*.
7. To initiate the data phase of the setup transaction (i.e., get the data for the `GET DEVICE DESCRIPTOR` command), set up a buffer in memory to store the received data.
8. Initialize the current (even or odd) RX or TX (RX for IN, TX for OUT) EP0 BD to transfer the data.
   a) Write C040h to BD0STAT. This sets the UOWN, configures Data Toggle (DTS) to DATA1 and sets the byte count to the length of the data buffer (64 or 40h in this case).
   b) Set BD0ADR to the starting address of the data buffer.
9. Write the Token register with the appropriate IN or OUT token to Endpoint 0, the target device's default control pipe (e.g., write 90h to U1TOK for an IN token for a `GET DEVICE DESCRIPTOR` command). This initiates an IN token on the bus followed by a data packet from the device to the host. When the data packet completes, the BD0STAT is written and a transfer done interrupt is asserted (the TRNIF flag is set). For control transfers with a single packet data phase, this completes the data phase of the setup transaction as referenced in *"Chapter 9 of the USB Specification"*. If more data needs to be transferred, return to step 8.
10. To initiate the status phase of the setup transaction, set up a buffer in memory to receive or send the zero length status phase data packet.
11. Initialize the current (even or odd) TX EP0 BD to transfer the status data:
    a) Set the BDT buffer address field to the start address of the data buffer.
    b) Write 8000h to BD0STAT (set UOWN bit, configure DTS to DATA0 and set byte count to 0).
12. Write the Token register with the appropriate IN or OUT token to Endpoint 0, the target device's default control pipe (e.g., write 01h to U1TOK for an OUT token for a `GET DEVICE DESCRIPTOR` command). This initiates an OUT token on the bus followed by a zero length data packet from the host to the device. When the data packet completes, the BD is updated with the handshake from the device and a transfer done interrupt is asserted (the TRNIF flag is set). This completes the status phase of the setup transaction as described in *"Chapter 9 of the USB Specification"*.

Note: Only one control transaction can be performed per frame.

19.0 ENHANCED PARALLEL MASTER PORT (EPMP)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the "*PIC24F Family Reference Manual*", **Section 42. "Enhanced Parallel Master Port (EPMP)"** (DS39730). The information in this data sheet supersedes the information in the FRM.

The Enhanced Parallel Master Port (EPMP) module is present in PIC24FJXXXDAX10 devices and not in PIC24FJXXXDAX06 devices. The EPMP provides a parallel 4-bit (Master mode only), 8-bit (Master and Slave modes) or 16-bit (Master mode only) data bus interface to communicate with off-chip modules, such as memories, FIFOs, LCD controllers and other microcontrollers. This module can serve as either the master or the slave on the communication bus. For EPMP Master modes, all external addresses are mapped into the internal Extended Data Space (EDS). This is done by allocating a region of the EDS for each chip select, and then assigning each chip select to a particular external resource, such as a memory or external controller. This region should not be assigned to another device resource, such as RAM or SFRs. To perform a write or read on an external resource, the CPU should simply perform a write or read within the address range assigned for EPMP.

Note: The EPMP module is not present in 64-pin devices (PIC24FJXXXDAX06).

The EPMP has an alternative master feature. The graphics controller module can control the EPMP directly in Alternate Master mode to access an external graphics buffer.

Key features of the EPMP module are:

- Extended Data Space (EDS) interface allows Direct Access from the CPU
- Up to 23 Programmable Address Lines
- Up to 2 Chip Select Lines
- Up to 2 Acknowledgement Lines (one per chip select)
- 4-bit, 8-bit or 16-bit wide Data Bus
- Programmable Strobe Options (per chip select)
  - Individual Read and Write Strobes or;
  - Read/$\overline{\text{Write}}$ Strobe with Enable Strobe
- Programmable Address/Data Multiplexing
- Programmable Address Wait States
- Programmable Data Wait States (per chip select)
- Programmable Polarity on Control Signals (per chip select)
- Legacy Parallel Slave Port Support
- Enhanced Parallel Slave Support
  - Address Support
  - 4-Byte Deep Auto-Incrementing Buffer
- Alternate Master feature

19.1 $\overline{\text{ALTPMP}}$ Setting

Many of the lower order EPMP address pins are shared with ADC inputs. This is an untenable situation for users that need both the ADC channels and the EPMP bus. If the user does not need to use all the address bits, then by clearing the $\overline{\text{ALTPMP}}$ (CW3<12>) Configuration bit, the lower order address bits can be mapped to higher address pins, which frees the ADC channels.

26.0 CHARGE TIME MEASUREMENT UNIT (CTMU)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the associated "*PIC24F Family Reference Manual*", **Section 11. "Charge Time Measurement Unit (CTMU)"** (DS39724). The information in this data sheet supersedes the information in the FRM.

The Charge Time Measurement Unit (CTMU) is a flexible analog module that provides accurate differential time measurement between pulse sources, as well as asynchronous pulse generation. Its key features include:

- Four edge input trigger sources
- Polarity control for each edge source
- Control of edge sequence
- Control of response to edges
- Time measurement resolution of 1 nanosecond
- Accurate current source suitable for capacitive measurement

Together with other on-chip analog modules, the CTMU can be used to precisely measure time, measure capacitance, measure relative changes in capacitance or generate output pulses that are independent of the system clock. The CTMU module is ideal for interfacing with capacitive-based sensors.

The CTMU is controlled through two registers: CTMUCON and CTMUICON. CTMUCON enables the module, and controls edge source selection, edge source polarity selection, and edge sequencing. The CTMUICON register controls the selection and trim of the current source.

26.1 Measuring Capacitance

The CTMU module measures capacitance by generating an output pulse with a width equal to the time between edge events on two separate input channels. The pulse edge events to both input channels can be selected from four sources: two internal peripheral modules (OC1 and Timer1) and two external pins (CTEDG1 and CTEDG2). This pulse is used with the module's precision current source to calculate capacitance according to the relationship:

$$C = I \cdot \frac{dV}{dT}$$

For capacitance measurements, the A/D Converter samples an external capacitor (C_{APP}) on one of its input channels after the CTMU output's pulse. A precision resistor (R_{PR}) provides current source calibration on a second A/D channel. After the pulse ends, the converter determines the voltage on the capacitor. The actual calculation of capacitance is performed in software by the application.

Figure 26-1 shows the external connections used for capacitance measurements, and how the CTMU and A/D modules are related in this application. This example also shows the edge events coming from Timer1, but other configurations using external edge sources are possible. A detailed discussion on measuring capacitance and time with the CTMU module is provided in the "*PIC24F Family Reference Manual*".

27.2 On-Chip Voltage Regulator

All PIC24FJ256DA210 family devices power their core digital logic at a nominal 1.8V. This may create an issue for designs that are required to operate at a higher typical voltage, such as 3.3V. To simplify system design, all devices in the PIC24FJ256DA210 family incorporate an on-chip regulator that allows the device to run its core logic from VDD.

The regulator is controlled by the ENVREG pin. Tying VDD to the pin enables the regulator, which in turn, provides power to the core from the other VDD pins. When the regulator is enabled, a low-ESR capacitor (such as ceramic) must be connected to the VCAP pin (Figure 27-1). This helps to maintain the stability of the regulator. The recommended value for the filter capacitor (CEFC) is provided in **Section 30.1 "DC Characteristics"**.

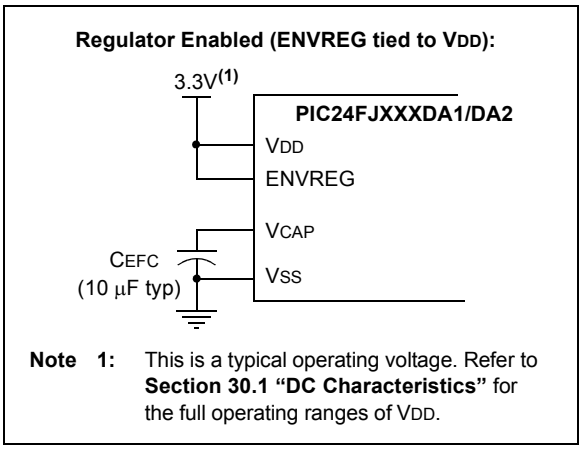
27.2.1 VOLTAGE REGULATOR LOW-VOLTAGE DETECTION

When the on-chip regulator is enabled, it provides a constant voltage of 1.8V nominal to the digital core logic.

The regulator can provide this level from a VDD of about 2.1V, all the way up to the device's VDDMAX. It does not have the capability to boost VDD levels. In order to prevent "brown-out" conditions when the voltage drops too low for the regulator, the Brown-out Reset occurs. Then the regulator output follows VDD with a typical voltage drop of 300 mV.

To provide information about when the regulator voltage starts reducing, the on-chip regulator includes a simple Low-Voltage Detect circuit, which sets the Low-Voltage Detect Interrupt Flag, LVDIF (IFS4<8>). This can be used to generate an interrupt to trigger an orderly shutdown.

FIGURE 27-1: CONNECTIONS FOR THE ON-CHIP REGULATOR



Note 1: This is a typical operating voltage. Refer to **Section 30.1 "DC Characteristics"** for the full operating ranges of VDD.

27.2.2 ON-CHIP REGULATOR AND POR

When the voltage regulator is enabled, it takes approximately 10 μs for it to generate output. During this time, designated as TVREG, code execution is disabled. TVREG is applied every time the device resumes operation after any power-down, including Sleep mode. TVREG is determined by the status of the VREGS bit (RCON<8>) and the WUTSEL Configuration bits (CW3<11:10>). Refer to **Section 30.0 "Electrical Characteristics"** for more information on TVREG.

TABLE 30-15: INTERNAL RC ACCURACY

AC CHARACTERISTICS		Standard Operating Conditions: 2.2V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial					
Param No.	Characteristic	Min	Typ	Max	Units	Conditions	
F20	**FRC Accuracy @ 8 MHz(1,2)**	-1	±0.15	1	%	-40°C ≤ TA ≤ +85°C	2.2V ≤ VDD ≤ 3.6V
F21	**LPRC @ 31 kHz**	-20	—	20	%	-40°C ≤ TA ≤ +85°C	VCAP (on-chip regulator output voltage) = 1.8V

Note 1: Frequency calibrated at 25°C and 3.3V. OSCTUN bits can be used to compensate for temperature drift.

2: To achieve this accuracy, physical stress applied to the microcontroller package (ex., by flexing the PCB) must be kept to a minimum.
