
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	PIC
Core Size	16-Bit
Speed	32MHz
Connectivity	I²C, IrDA, SPI, UART/USART, USB OTG
Peripherals	Brown-out Detect/Reset, GFX, LVD, POR, PWM, WDT
Number of I/O	52
Program Memory Size	128KB (43K x 24)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	96K x 8
Voltage - Supply (Vcc/Vdd)	2.2V ~ 3.6V
Data Converters	A/D 16x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	64-VFQFN Exposed Pad
Supplier Device Package	64-VQFN (9x9)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic24fj128da206-i-mr

TABLE 1-3: PIC24FJ256DA210 FAMILY PINOUT DESCRIPTIONS (CONTINUED)

Function	Pin Number			I/O	Input Buffer	Description
	64-Pin TQFP/QFN	100-Pin TQFP	121-Pin BGA			
RB0	16	25	K2	I/O	ST	PORTB Digital I/O.
RB1	15	24	K1	I/O	ST	
RB2	14	23	J2	I/O	ST

RB4	12	21	H2	I/O	ST	
RB5	11	20	H1	I/O	ST	
RB6	17	26	L1	I/O	ST	
RB7	18	27	J3	I/O	ST	
RB8	21	32	K4	I/O	ST	
RB9	22	33	L4	I/O	ST	
RB10	23	34	L5	I/O	ST	
RB11	24	35	J5	I/O	ST	
RB12	27	41	J7	I/O	ST	
RB13	28	42	L7	I/O	ST	
RB14	29	43	K7	I/O	ST	
RB15	30	44	L8	I/O	ST	
RC1	—	6	D1	I/O	ST	PORTC Digital I/O.
RC2	—	7	E4	I/O	ST	
RC3	—	8	E2	I/O	ST	
RC4	—	9	E1	I/O	ST	
RC12	39	63	F9	I/O	ST	
RC13	47	73	C10	I/O	ST	
RC14	48	74	B11	I/O	ST	
RC15	40	64	F11	I/O	ST	
RCV	18	27	J3	I	ST	USB Receive Input (from external transceiver).

Legend: TTL = TTL input buffer; ST = Schmitt Trigger input buffer; ANA = Analog level input/output; I^2C™ = I^2C/SMBus input buffer

Note 1: The alternate EPMP pins are selected when the $\overline{\text{ALTPMP}}$ (CW3<12>) bit is programmed to '0'.

2: The PMSC2 signal will replace the PMA15 signal on the 15-pin PMA when CSF<1:0> = 01 or 10.

3: The PMCS1 signal will replace the PMA14 signal on the 14-pin PMA when CSF<1:0> = 10.

4: The alternate VREF pins selected when the $\overline{\text{ALTVREF}}$ (CW1<5>) bit is programmed to '0'.

VHOLD = 1: The VECNUM bits indicate the vector number (from 0 to 118) of the last interrupt to occur
VHOLD = 0: The VECNUM bits indicate the vector number (from 0 to 118) of the interrupt request currently being handled

8.0 OSCILLATOR CONFIGURATION

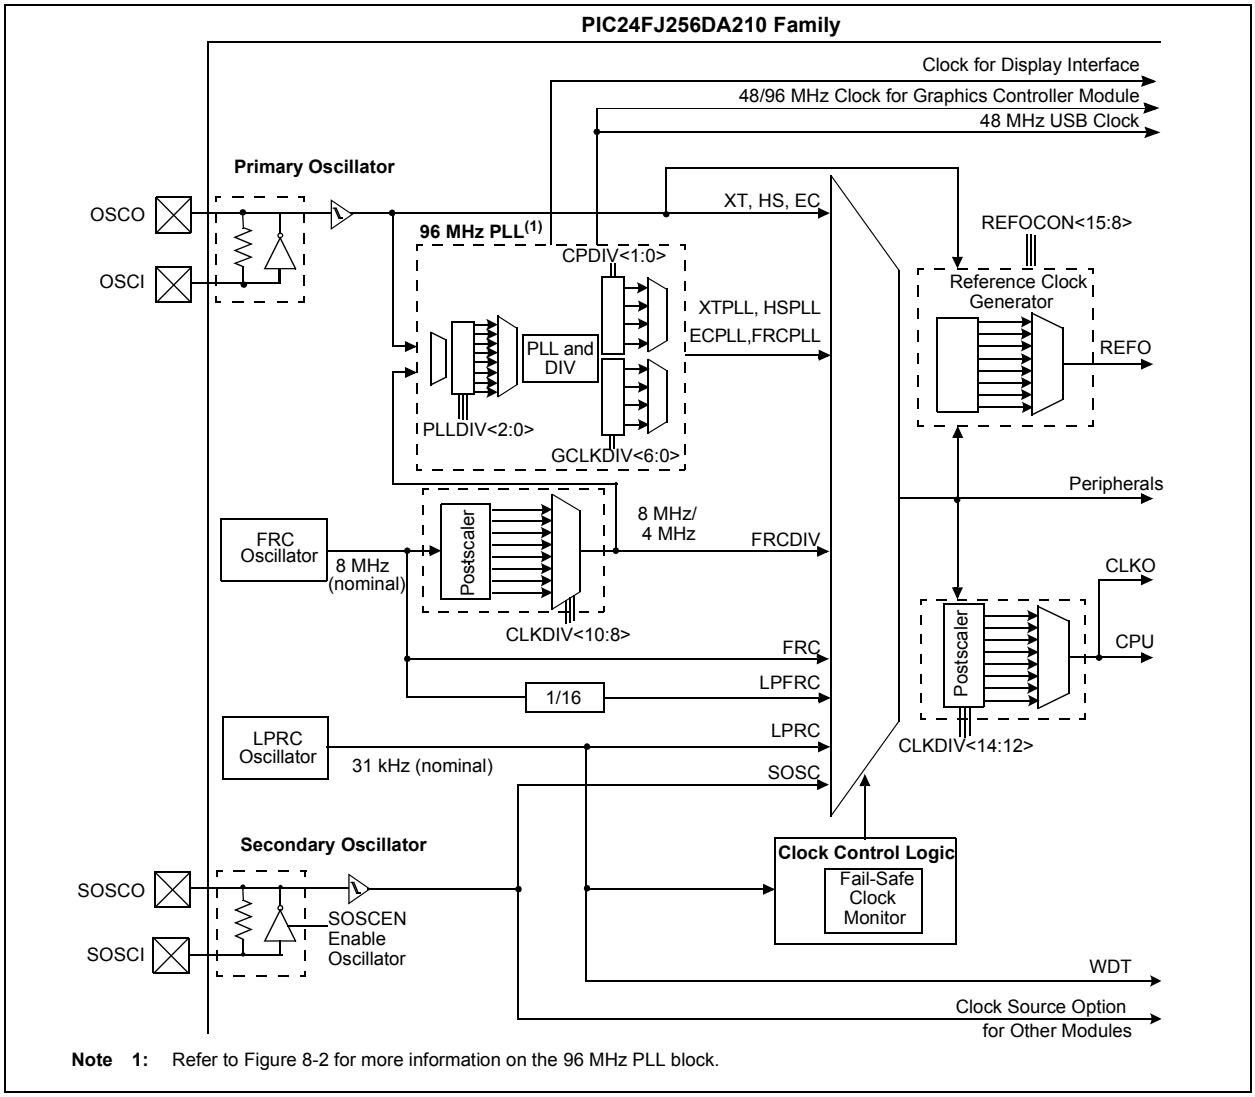
Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the *"PIC24F Family Reference Manual"*, **Section 6. "Oscillator"** (DS39700). The information in this data sheet supersedes the information in the FRM.

The oscillator system for PIC24FJ256DA210 family devices has the following features:

- A total of four external and internal oscillator options as clock sources, providing 11 different clock modes
- An on-chip PLL block to boost internal operating frequency on select internal and external oscillator sources, and to provide a precise clock source for peripherals, such as USB and graphics
- Software controllable switching between various clock sources
- Software controllable postscaler for selective clocking of CPU for system power savings
- A Fail-Safe Clock Monitor (FSCM) that detects clock failure and permits safe application recovery or shutdown
- A separate and independently configurable system clock output for synchronizing external hardware

A simplified diagram of the oscillator system is shown in Figure 8-1.

FIGURE 8-1: PIC24FJ256DA210 FAMILY CLOCK DIAGRAM



Note 1: Refer to Figure 8-2 for more information on the 96 MHz PLL block.

10.1.1 I/O PORT WRITE/READ TIMING

One instruction cycle is required between a port direction change or port write operation and a read operation of the same port. Typically, this instruction would be a NOP.

10.1.2 OPEN-DRAIN CONFIGURATION

In addition to the PORT, LAT and TRIS registers for data control, each port pin can also be individually configured for either a digital or open-drain output. This is controlled by the Open-Drain Control register, ODCx, associated with each port. Setting any of the bits configures the corresponding pin to act as an open-drain output.

The open-drain feature allows the generation of outputs higher than VDD (e.g., 5V) on any desired digital only pins by using external pull-up resistors. The maximum open-drain voltage allowed is the same as the maximum VIH specification.

10.1.3 CONFIGURING D+ AND D- PINS (RG2 AND RG3)

The input buffers of the RG2 and RG3 pins are by default, tri-stated. To use these pins as input pins, the UTRDIS bit (U1CNFG2<0>) should be set which enables the input buffers on these pins.

10.2 Configuring Analog Port Pins (ANSEL)

The ANSx and TRISx registers control the operation of the pins with analog function. Each port pin with analog function is associated with one of the ANS bits (see Register 10-1 through Register 10-7), which decides if the pin function should be analog or digital. Refer to Table 10-1 for detailed behavior of the pin for different ANSx and TRISx bit settings.

When reading the PORT register, all pins configured as analog input channels will read as cleared (a low level).

10.2.1 ANALOG INPUT PINS AND VOLTAGE CONSIDERATIONS

The voltage tolerance of pins used as device inputs is dependent on the pin's input function. Pins that are used as digital only inputs are able to handle DC voltages of up to 5.5V, a level typical for digital logic circuits. In contrast, pins that also have analog input functions of any kind can only tolerate voltages up to VDD. Voltage excursions beyond VDD on these pins should always be avoided. Table 10-2 summarizes the input capabilities. Refer to **Section 30.1 "DC Characteristics"** for more details.

TABLE 10-1: CONFIGURING ANALOG/DIGITAL FUNCTION OF AN I/O PIN

Pin Function	ANSx Setting	TRISx Setting	Comments
Analog Input	1	1	It is recommended to keep ANSx = 1.
Analog Output	1	1	It is recommended to keep ANSx = 1.
Digital Input	0	1	Firmware must wait at least one instruction cycle after configuring a pin as a digital input before a valid input value can be read.
Digital Output	0	0	Make sure to disable the analog output function on the pin if any is present.

TABLE 10-2: INPUT VOLTAGE LEVELS FOR PORT OR PIN TOLERATED DESCRIPTION INPUT

Port or Pin	Tolerated Input	Description
PORTA(1)<10:9, 7:6>	VDD	Only VDD input levels are tolerated.
PORTB<15:0>		
PORTC(1)<15:12, 4>		
PORTD<7:6>		
PORTE(1)<9>		
PORTF<0>		
PORTG<9:6, 3:2>		
PORTA(1)<15:14, 5:0>	5.5V	Tolerates input levels above VDD, useful for most standard logic.
PORTC(1)<3:1>		
PORTD(1)<15:8, 5:0>		
PORTE(1)<8:0>		
PORTF(1)<13:12, 8:7, 5:1>		
PORTG(1)<15:12, 1:0>		

Note 1: Not all of the pins of these PORTS are implemented in 64-pin devices (PIC24FJXXXDAX06); refer to the device pinout diagrams for the details.

For 32-bit cascaded operation, these steps are also necessary:

1. Set the OC32 bits for both registers (OCyCON2<8>) and (OCxCON2<8>). Enable the even numbered module first to ensure the modules will start functioning in unison.
2. Clear the OCTRIG bit of the even module (OCyCON2), so the module will run in Synchronous mode.
3. Configure the desired output and Fault settings for OCy.
4. Force the output pin for OCx to the output state by clearing the OCTRIS bit.
5. If Trigger mode operation is required, configure the trigger options in OCx by using the OCTRIG (OCxCON2<7>), TRIGMODE (OCxCON1<3>) and SYNCSEL (OCxCON2<4:0>) bits.
6. Configure the desired Compare or PWM mode of operation (OCM<2:0>) for OCy first, then for OCx.

Depending on the output mode selected, the module holds the OCx pin in its default state and forces a transition to the opposite state when OCxR matches the timer. In Double Compare modes, OCx is forced back to its default state when a match with OCxRS occurs. The OCxIF interrupt flag is set after an OCxR match in Single Compare modes and after each OCxRS match in Double Compare modes.

Single-shot pulse events only occur once, but may be repeated by simply rewriting the value of the OCxCON1 register. Continuous pulse events continue indefinitely until terminated.

14.3 Pulse-Width Modulation (PWM) Mode

In PWM mode, the output compare module can be configured for edge-aligned or center-aligned pulse waveform generation. All PWM operations are double-buffered (buffer registers are internal to the module and are not mapped into SFR space).

To configure the output compare module for PWM operation:

1. Configure the OCx output for one of the available Peripheral Pin Select pins.
2. Calculate the desired duty cycles and load them into the OCxR register.
3. Calculate the desired period and load it into the OCxRS register.
4. Select the current OCx as the synchronization source by writing 0x1F to the SYNCSEL<4:0> bits (OCxCON2<4:0>) and '0' to the OCTRIG bit (OCxCON2<7>).
5. Select a clock source by writing to the OCTSEL<2:0> bits (OCxCON<12:10>).
6. Enable interrupts, if required, for the timer and output compare modules. The output compare interrupt is required for PWM Fault pin utilization.
7. Select the desired PWM mode in the OCM<2:0> bits (OCxCON1<2:0>).
8. Appropriate Fault inputs may be enabled by using the ENFLT<2:0> bits as described in Register 14-1.
9. If a timer is selected as a clock source, set the selected timer prescale value. The selected timer's prescaler output is used as the clock input for the OCx timer, and not the selected timer output.

Note:	This peripheral contains input and output functions that may need to be configured by the Peripheral Pin Select. See **Section 10.4 "Peripheral Pin Select (PPS)"** for more information.

1 = J state (differential '0' in low speed, differential '1' in full speed) is detected on the USB
0 = No J state is detected

bit 6 **SE0:** Live Single-Ended Zero Flag bit
1 = Single-ended zero is active on the USB bus
0 = No single-ended zero is detected

bit 5 **TOKBUSY:** Token Busy Status bit
1 = Token is being executed by the USB module in On-The-Go state
0 = No token is being executed

bit 4 **USBRST:** Module Reset bit
1 = USB Reset has been generated; for software Reset, application must set this bit for 50 ms, then clear it
0 = USB Reset is terminated

bit 3 **HOSTEN:** Host Mode Enable bit
1 = USB host capability is enabled; pull-downs on D+ and D- are activated in hardware
0 = USB host capability is disabled

bit 2 **RESUME:** Resume Signaling Enable bit
1 = Resume signaling is activated; software must set bit for 10 ms and then clear to enable remote wake-up
0 = Resume signaling is disabled

bit 1 **PPBRST:** Ping-Pong Buffers Reset bit
1 = Reset all Ping-Pong Buffer Pointers to the even BD banks
0 = Ping-Pong Buffer Pointers are not reset

bit 0 **SOFEN:** Start-Of-Frame Enable bit
1 = Start-Of-Frame token is sent every one 1 ms
0 = Start-Of-Frame token is disabled

20.2 Calibration

The real-time crystal input can be calibrated using the periodic auto-adjust feature. When properly calibrated, the RTCC can provide an error of less than 3 seconds per month. This is accomplished by finding the number of error clock pulses for one minute and storing the value into the lower half of the RCFGCAL register. The 8-bit signed value loaded into the lower half of RCFGCAL is multiplied by four and will either be added or subtracted from the RTCC timer, once every minute. Refer to the following steps for RTCC calibration:

1. Using another timer resource on the device, the user must find the error of the 32.768 kHz crystal.
2. Once the error is known, it must be converted to the number of error clock pulses per minute and loaded into the RCFGCAL register.

EQUATION 20-1: RTCC CALIBRATION

Error (clocks per minute) = (Ideal Frequency† – Measured Frequency) x 60

†Ideal Frequency = 32,768H

3. a) If the oscillator is faster then ideal (negative result form Step 2), the RCFGCAL register value needs to be negative. This causes the specified number of clock pulses to be subtracted from the timer counter, once every minute.

   b) If the oscillator is slower then ideal (positive result from Step 2), the RCFGCAL register value needs to be positive. This causes the specified number of clock pulses to be added to the timer counter, once every minute.
4. Divide the number of error clocks per minute by 4 to get the correct CAL value and load the RCFGCAL register with the correct value.

   (Each 1-bit increment in CAL adds or subtracts 4 pulses).

Writes to the lower half of the RCFGCAL register should only occur when the timer is turned off or immediately after the rising edge of the seconds pulse.

Note:	It is up to the user to include in the error value the initial error of the crystal, drift due to temperature and drift due to crystal aging.

20.3 Alarm

- Configurable from half second to one year
- Enabled using the ALRMEN bit (ALCFGRPT<15>, Register 20-3)
- One-time alarm and repeat alarm options available

20.3.1 CONFIGURING THE ALARM

The alarm feature is enabled using the ALRMEN bit. This bit is cleared when an alarm is issued. Writes to ALRMVAL should only take place when ALRMEN = 0.

As shown in Figure 20-2, the interval selection of the alarm is configured through the AMASK bits (ALCFGRPT<13:10>). These bits determine which and how many digits of the alarm must match the clock value for the alarm to occur.

The alarm can also be configured to repeat based on a preconfigured interval. The amount of times this occurs, once the alarm is enabled, is stored in the ARPT bits, ARPT<7:0> (ALCFGRPT<7:0>). When the value of the ARPT bits equals 00h and the CHIME bit (ALCFGRPT<14>) is cleared, the repeat function is disabled and only a single alarm will occur. The alarm can be repeated up to 255 times by loading ARPT<7:0> with FFh.

After each alarm is issued, the value of the ARPT bits is decremented by one. Once the value has reached 00h, the alarm will be issued one last time, after which the ALRMEN bit will be cleared automatically and the alarm will turn off.

Indefinite repetition of the alarm can occur if the CHIME bit = 1. Instead of the alarm being disabled when the value of the ARPT bits reaches 00h, it rolls over to FFh and continues counting indefinitely while CHIME is set.

20.3.2 ALARM INTERRUPT

At every alarm event, an interrupt is generated. In addition, an alarm pulse output is provided that operates at half the frequency of the alarm. This output is completely synchronous to the RTCC clock and can be used as a trigger clock to other peripherals.

Note:	Changing any of the registers, other then the RCFGCAL and ALCFGRPT registers and the CHIME bit while the alarm is enabled (ALRMEN = 1), can result in a false alarm event leading to a false alarm interrupt. To avoid a false alarm event, the timer and alarm values should only be changed while the alarm is disabled (ALRMEN = 0). It is recommended that the ALCFGRPT register and CHIME bit be changed when RTCSYNC = 0.

bit 0 **BFINAL:** Final Block Encountered Status bit(1,2)
- 1 = Final block is encountered
- 0 = Final block is not encountered

Note 1: IPUDONE and BFINAL status bits are set after successful decompression.

2: All IPU status bits are available after each decompression. All status bits are automatically cleared every time a decompression command (IPU_DECOMPRESS) is issued.

27.4 Program Verification and Code Protection

PIC24FJ256DA210 family devices provide two complimentary methods to protect application code from overwrites and erasures. These also help to protect the device from inadvertent configuration changes during run time.

27.4.1 GENERAL SEGMENT PROTECTION

For all devices in the PIC24FJ256DA210 family, the on-chip program memory space is treated as a single block, known as the General Segment (GS). Code protection for this block is controlled by one Configuration bit, GCP. This bit inhibits external reads and writes to the program memory space. It has no direct effect in normal execution mode.

Write protection is controlled by the GWRP bit in the Configuration Word. When GWRP is programmed to '0', internal write and erase operations to program memory are blocked.

27.4.2 CODE SEGMENT PROTECTION

In addition to global General Segment protection, a separate subrange of the program memory space can be individually protected against writes and erases. This area can be used for many purposes where a separate block of write and erase-protected code is needed, such as bootloader applications. Unlike common boot block implementations, the specially protected segment in the PIC24FJ256DA210 family devices can be located by the user anywhere in the program space and configured in a wide range of sizes.

Code segment protection provides an added level of protection to a designated area of program memory by disabling the NVM safety interlock whenever a write or erase address falls within a specified range. It does not override General Segment protection controlled by the GCP or GWRP bits. For example, if GCP and GWRP are enabled, enabling segmented code protection for the bottom half of program memory does not undo General Segment protection for the top half.

The size and type of protection for the segmented code range are configured by the WPFPx, WPEND, WPCFG and WPDIS bits in Configuration Word 3. Code segment protection is enabled by programming the WPDIS bit (= 0). The WPFP bits specify the size of the segment to be protected, by specifying the 512-word code page that is the start or end of the protected segment. The specified region is inclusive, therefore, this page will also be protected.

The WPEND bit determines if the protected segment uses the top or bottom of the program space as a boundary. Programming WPEND (= 0) sets the bottom of program memory (000000h) as the lower boundary of the protected segment. Leaving WPEND unprogrammed (= 1) protects the specified page through the last page of implemented program memory, including the Configuration Word locations.

A separate bit, WPCFG, is used to protect the last page of program space, including the Flash Configuration Words. Programming WPCFG (= 0) protects the last page in addition to the pages selected by the WPEND and WPFP<7:0> bits setting. This is useful in circumstances where write protection is needed for both the code segment in the bottom of the memory and the Flash Configuration Words.

The various options for segment code protection are shown in Table 27-2.

TABLE 30-5: DC CHARACTERISTICS: IDLE CURRENT (IIDLE)

DC CHARACTERISTICS			Standard Operating Conditions: 2.2V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for Industrial			
Parameter No.	**Typical(1)**	**Max**	**Units**	**Conditions**		
Idle Current (IIDLE)(2)						
DC40D	170	320	μA	-40°C	3.3V(3)	1 MIPS
DC40E	170	320	μA	+25°C		
DC40F	220	380	μA	+85°C		
DC43D	0.6	1.2	mA	-40°C	3.3V(3)	4 MIPS
DC43E	0.6	1.2	mA	+25°C		
DC43F	0.7	1.2	mA	+85°C		
DC47D	2.3	4.8	mA	-40°C	3.3V(3)	16 MIPS
DC47E	2.3	4.8	mA	+25°C		
DC47F	2.4	4.8	mA	+85°C		
DC50D	0.8	1.8	mA	-40°C	3.3V(3)	FRC (4 MIPS)
DC50E	0.8	1.8	mA	+25°C		
DC50F	1.0	1.8	mA	+85°C		
DC51D	40.0	85	μA	-40°C	3.3V(3)	LPRC (31 kHz)
DC51E	40.0	85	μA	+25°C		
DC51F	120.0	210	μA	+85°C		

Note 1: Data in "Typical" column is at 3.3V, 25°C unless otherwise stated. Parameters are for design guidance only and are not tested.

2: Base IIDLE current is measured with the core off; OSCI driven with external square wave from rail to rail. All I/O pins are configured as inputs and pulled to VDD. $\overline{MCLR}$ = VDD; WDT and FSCM are disabled. No peripheral modules are operating and all of the Peripheral Module Disable (PMD) bits are set.

3: On-chip voltage regulator enabled (ENVREG tied to VDD). Brown-out Reset (BOR) is enabled.

NOTES:

100-Lead Plastic Thin Quad Flatpack (PT) – 12x12x1 mm Body, 2.00 mm [TQFP]
