

Welcome to [E-XFL.COM](http://E-XFL.COM)

### Understanding [Embedded - DSP \(Digital Signal Processors\)](#)

[Embedded - DSP \(Digital Signal Processors\)](#) are specialized microprocessors designed to perform complex mathematical computations on digital signals in real-time. Unlike general-purpose processors, DSPs are optimized for high-speed numeric processing tasks, making them ideal for applications that require efficient and precise manipulation of digital data. These processors are fundamental in converting and processing signals in various forms, including audio, video, and communication signals, ensuring that data is accurately interpreted and utilized in embedded systems.

### Applications of [Embedded - DSP \(Digital Signal Processors\)](#)

#### Details

Product Status	Obsolete
Type	Fixed Point
Interface	Synchronous Serial Port (SSP)
Clock Rate	52MHz
Non-Volatile Memory	External
On-Chip RAM	80kB
Voltage - I/O	3.30V
Voltage - Core	3.30V
Operating Temperature	0°C ~ 70°C (TA)
Mounting Type	Surface Mount
Package / Case	144-LFBGA
Supplier Device Package	144-MiniBGA (10x10)
Purchase URL	<a href="https://www.e-xfl.com/product-detail/analog-devices/adsp-2183kcaz-210">https://www.e-xfl.com/product-detail/analog-devices/adsp-2183kcaz-210</a>

# ADSP-2183

This takes place while the processor continues to:

- Receive and transmit data through the two serial ports
- Receive and/or transmit data through the internal DMA port
- Receive and/or transmit data through the byte DMA port
- Decrement timer

## Development System

The ADSP-2100 Family Development Software, a complete set of tools for software and hardware system development, supports the ADSP-2183. The assembler has an algebraic syntax that is easy to program and debug. The linker combines object files into an executable file. The simulator provides an interactive instruction-level simulation with a reconfigurable user interface to display different portions of the hardware environment.

The EZ-KIT Lite is a hardware/software kit offering a complete development environment for the ADSP-21xx family: an ADSP-2189M evaluation board with PC monitor software plus Assembler, Linker, Simulator and PROM Splitter software. The ADSP-2189M evaluation board is a low-cost, easy to use hardware platform on which you can quickly get started with your DSP software design. The EZ-KIT Lite include the following features:

- 35.7 MHz ADSP-2189M
- Full 16-bit Stereo Audio I/O with AD73322 CODEC
- RS-232 Interface
- EZ-ICE Connector for Emulator Control
- DSP Demo Programs
- Evaluation Suite of VisualDSP

The ADSP-218x EZ-ICE<sup>®</sup> Emulator aids in the hardware debugging of ADSP-218x systems. The ADSP-218x integrates on-chip emulation support with a 14-pin ICE-Port interface. This interface provides a simpler target board connection requiring fewer mechanical clearance considerations than other ADSP-2100 Family EZ-ICEs. The ADSP-218x device need not be removed from the target system when using the EZ-ICE, nor are any adapters needed. Due to the small footprint of the EZ-ICE connector, emulation can be supported in final board designs.

The EZ-ICE performs a full range of functions, including:

- In-target operation
- Up to 20 breakpoints
- Single-step or full-speed operation
- Registers and memory values can be examined and altered
- PC upload and download functions
- Instruction-level emulation of program booting and execution
- Complete assembly and disassembly of instructions
- C source-level debugging

(See Designing An EZ-ICE-Compatible Target System section of this data sheet for exact specifications of the EZ-ICE target board connector.)

## Additional Information

This data sheet provides a general overview of ADSP-2183 functionality. For additional information on the architecture and instruction set of the processor, refer to the *ADSP-2100 Family User's Manual*, Third Edition. For more information about the development tools, refer to the *ADSP-2100 Family Development Tools Data Sheet*.

## ARCHITECTURE OVERVIEW

The ADSP-2183 instruction set provides flexible data moves and multifunction (one or two data moves with a computation) instructions. Every instruction can be executed in a single processor cycle. The ADSP-2183 assembly language uses an algebraic syntax for ease of coding and readability. A comprehensive set of development tools supports program development.

Figure 1 is an overall block diagram of the ADSP-2183. The processor contains three independent computational units: the ALU, the multiplier/accumulator (MAC) and the shifter. The computational units process 16-bit data directly and have provisions to support multiprecision computations. The ALU performs a standard set of arithmetic and logic operations; division primitives are also supported. The MAC performs single-cycle multiply, multiply/add and multiply/subtract operations with 40 bits of accumulation. The shifter performs logical and arithmetic shifts, normalization, denormalization and derive exponent operations. The shifter can be used to efficiently implement numeric format control including multiword and block floating-point representations.

The internal result (R) bus connects the computational units so that the output of any unit may be the input of any unit on the next cycle.

The ADSP-21xx family DSPs contain a shadow register that is useful for single cycle context switching of the processor.

A powerful program sequencer and two dedicated data address generators ensure efficient delivery of operands to these computational units. The sequencer supports conditional jumps, subroutine calls and returns in a single cycle. With internal loop counters and loop stacks, the ADSP-2183 executes looped code with zero overhead; no explicit jump instructions are required to maintain loops.

Two data address generators (DAGs) provide addresses for simultaneous dual operand fetches (from data memory and program memory). Each DAG maintains and updates four address pointers. Whenever the pointer is used to access data (indirect addressing), it is post-modified by the value of one of four possible modify registers. A length value may be associated with each pointer to implement automatic modulo addressing for circular buffers.

Efficient data transfer is achieved with the use of five internal buses:

- Program Memory Address (PMA) Bus
- Program Memory Data (PMD) Bus
- Data Memory Address (DMA) Bus
- Data Memory Data (DMD) Bus
- Result (R) Bus

The two address buses (PMA and DMA) share a single external address bus, allowing memory to be expanded off-chip, and the two data buses (PMD and DMD) share a single external data bus. Byte memory space and I/O memory space also share the external buses.

Program memory can store both instructions and data, permitting the ADSP-2183 to fetch two operands in a single cycle, one from program memory and one from data memory. The ADSP-2183 can fetch an operand from program memory and the next instruction in the same cycle.

In addition to the address and data bus for external memory connection, the ADSP-2183 has a 16-bit Internal DMA port (IDMA port) for connection to external systems. The IDMA port is made up of 16 data/address pins and five control pins. The IDMA port provides transparent, direct access to the DSP's on-chip program and data RAM.

An interface to low cost byte-wide memory is provided by the Byte DMA port (BDMA port). The BDMA port is bidirectional and can directly address up to four megabytes of external RAM or ROM for off-chip storage of program overlays or data tables.

The byte memory and I/O memory space interface supports slow memories and I/O memory-mapped peripherals with programmable wait state generation. External devices can gain control of external buses with bus request/grant signals ( $\overline{BR}$ ,  $\overline{BGH}$  and  $\overline{BG}$ ). One execution mode (Go Mode) allows the ADSP-2183 to continue running from on-chip memory. Normal execution mode requires the processor to halt while buses are granted.

The ADSP-2183 can respond to thirteen possible interrupts, eleven of which are accessible at any given time. There can be up to six external interrupts (one edge-sensitive, two level-sensitive and three configurable) and seven internal interrupts generated by the timer, the serial ports (SPORTs), the Byte DMA port and the power-down circuitry. There is also a master  $\overline{RESET}$  signal.

The two serial ports provide a complete synchronous serial interface with optional companding in hardware and a wide variety of framed or frameless data transmit and receive modes of operation. Each port can generate an internal programmable serial clock or accept an external serial clock.

The ADSP-2183 provides up to 13 general-purpose flag pins. The data input and output pins on SPORT1 can be alternatively configured as an input flag and an output flag. In addition, eight flags are programmable as inputs or outputs and three flags are always outputs.

A programmable interval timer generates periodic interrupts. A 16-bit count register (TCOUNT) is decremented every  $n$  processor cycle, where  $n$  is a scaling value stored in an 8-bit register (TSCALE). When the value of the count register reaches zero, an interrupt is generated and the count register is reloaded from a 16-bit period register (TPERIOD).

### Serial Ports

The ADSP-2183 incorporates two complete synchronous serial ports (SPORT0 and SPORT1) for serial communications and multiprocessor communication.

Here is a brief list of the capabilities of the ADSP-2183 SPORTs. Refer to the *ADSP-2100 Family User's Manual*, Third Edition, for further details.

- SPORTs are bidirectional and have a separate, double-buffered transmit and receive section.
- SPORTs can use an external serial clock or generate their own serial clock internally.
- SPORTs have independent framing for the receive and transmit sections. Sections run in a frameless mode or with frame synchronization signals, internally or externally generated. Frame sync signals are active high or inverted, with either of two pulsewidths and timings.

Figure 1. Block Diagram

# ADSP-2183

- SPORTs support serial data word lengths from 3 to 16 bits and provide optional A-law and  $\mu$ -law companding according to CCITT recommendation G.711.
- SPORT receive and transmit sections can generate unique interrupts on completing a data word transfer.
- SPORTs can receive and transmit an entire circular buffer of data with only one overhead cycle per data word. An interrupt is generated after a data buffer transfer.
- SPORT0 has a multichannel interface to selectively receive and transmit a 24 or 32 word, time-division multiplexed, serial bitstream.
- SPORT1 can be configured to have two external interrupts ( $\overline{\text{IRQ0}}$  and  $\overline{\text{IRQ1}}$ ) and the Flag In and Flag Out signals. The internally generated serial clock may still be used in this configuration.

## Pin Descriptions

The ADSP-2183 is available in a 128-lead LQFP package, and Mini-BGA.

### PIN FUNCTION DESCRIPTIONS

Pin Name(s)	# of Pins	Input/Output	Function
Address	14	O	Address Output Pins for Program, Data, Byte, & I/O Spaces
Data	24	I/O	Data I/O Pins for Program and Data Memory Spaces (8 MSBs Are Also Used as Byte Space Addresses)
$\overline{\text{RESET}}$	1	I	Processor Reset Input
$\overline{\text{IRQ2}}$	1	I	Edge- or Level-Sensitive Interrupt Request
$\overline{\text{IRQL0}}$ , $\overline{\text{IRQL1}}$	2	I	Level-Sensitive Interrupt Requests
$\overline{\text{IRQE}}$	1	I	Edge-Sensitive Interrupt Request
$\overline{\text{BR}}$	1	I	Bus Request Input
$\overline{\text{BG}}$	1	O	Bus Grant Output
$\overline{\text{BGH}}$	1	O	Bus Grant Hung Output
$\overline{\text{PMS}}$	1	O	Program Memory Select Output
$\overline{\text{DMS}}$	1	O	Data Memory Select Output
$\overline{\text{BMS}}$	1	O	Byte Memory Select Output
$\overline{\text{IOMS}}$	1	O	I/O Space Memory Select Output
$\overline{\text{CMS}}$	1	O	Combined Memory Select Output
$\overline{\text{RD}}$	1	O	Memory Read Enable Output
$\overline{\text{WR}}$	1	O	Memory Write Enable Output
MMAP	1	I	Memory Map Select Input
BMODE	1	I	Boot Option Control Input
CLKIN, XTAL	2	I	Clock or Quartz Crystal Input

Pin Name(s)	# of Pins	Input/Output	Function
CLKOUT	1	O	Processor Clock Output.
SPORT0	5	I/O	Serial Port I/O Pins
SPORT1	5	I/O	Serial Port 1 or Two External $\overline{\text{IRQs}}$ , Flag In and Flag Out
$\overline{\text{IRD}}$ , $\overline{\text{IWR}}$	2	I	IDMA Port Read/Write Inputs
$\overline{\text{IS}}$	1	I	IDMA Port Select
IAL	1	I	IDMA Port Address Latch Enable
IAD	16	I/O	IDMA Port Address/Data Bus
$\overline{\text{IACK}}$	1	O	IDMA Port Access Ready Acknowledge
$\overline{\text{PWD}}$	1	I	Power-Down Control
PWDACK	1	O	Power-Down Control
FL0, FL1, FL2	3	O	Output Flags
PF7:0	8	I/O	Programmable I/O Pins
EE	1	*	(Emulator Only*)
$\overline{\text{EBR}}$	1	*	(Emulator Only*)
$\overline{\text{EBG}}$	1	*	(Emulator Only*)
$\overline{\text{ERESET}}$	1	*	(Emulator Only*)
$\overline{\text{EMS}}$	1	*	(Emulator Only*)
$\overline{\text{EINT}}$	1	*	(Emulator Only*)
ECLK	1	*	(Emulator Only*)
ELIN	1	*	(Emulator Only*)
ELOUT	1	*	(Emulator Only*)
GND	11		Ground Pins (LQFP)
VDD	6		Power Supply Pins (LQFP)
GND	22		Ground Pins (Mini-BGA)
VDD	11		Power Supply Pins (Mini-BGA)

\*These ADSP-2183 pins must be connected *only* to the EZ-ICE connector in the target system. These pins have no function except during emulation, and do not require pull-up or pull-down resistors.

## Interrupts

The interrupt controller allows the processor to respond to the eleven possible interrupts and reset with minimum overhead. The ADSP-2183 provides four dedicated external interrupt input pins,  $\overline{\text{IRQ2}}$ ,  $\overline{\text{IRQL0}}$ ,  $\overline{\text{IRQL1}}$  and  $\overline{\text{IRQE}}$ . In addition, SPORT1 may be reconfigured for  $\overline{\text{IRQ0}}$ ,  $\overline{\text{IRQ1}}$ , FLAG\_IN and FLAG\_OUT, for a total of six external interrupts. The ADSP-2183 also supports internal interrupts from the timer, the byte DMA port, the two serial ports, software and the power-down control circuit. The interrupt levels are internally prioritized and individually maskable (except power-down and reset). The  $\overline{\text{IRQ2}}$ ,  $\overline{\text{IRQ0}}$  and  $\overline{\text{IRQ1}}$  input pins can be programmed to be either level- or edge-sensitive.  $\overline{\text{IRQL0}}$  and  $\overline{\text{IRQL1}}$  are level-sensitive and  $\overline{\text{IRQE}}$  is edge sensitive. The priorities and vector addresses of all interrupts are shown in Table I.

**Table I. Interrupt Priority and Interrupt Vector Addresses**

Source of Interrupt	Interrupt Vector Address (Hex)
Reset (or Power-Up with PUCR = 1)	0000 ( <i>Highest Priority</i> )
Power-Down (Nonmaskable)	002C
$\overline{IRQ2}$	0004
$\overline{IRQL1}$	0008
$\overline{IRQL0}$	000C
SPORT0 Transmit	0010
SPORT0 Receive	0014
$\overline{IRQE}$	0018
BDMA Interrupt	001C
SPORT1 Transmit or $\overline{IRQ1}$	0020
SPORT1 Receive or $\overline{IRQ0}$	0024
Timer	0028 ( <i>Lowest Priority</i> )

Interrupt routines can either be nested, with higher priority interrupts taking precedence, or processed sequentially. Interrupts can be masked or unmasked with the IMASK register. Individual interrupt requests are logically ANDed with the bits in IMASK; the highest priority unmasked interrupt is then selected. The power-down interrupt is nonmaskable.

The ADSP-2183 masks all interrupts for one instruction cycle following the execution of an instruction that modifies the IMASK register. This does not affect serial port autobuffering or DMA transfers.

The interrupt control register, ICNTL, controls interrupt nesting and defines the  $\overline{IRQ0}$ ,  $\overline{IRQ1}$  and  $\overline{IRQ2}$  external interrupts to be either edge- or level-sensitive. The  $\overline{IRQE}$  pin is an external edge-sensitive interrupt and can be forced and cleared. The  $\overline{IRQL0}$  and  $\overline{IRQL1}$  pins are external level-sensitive interrupts.

The IFC register is a write-only register used to force and clear interrupts.

On-chip stacks preserve the processor status and are automatically maintained during interrupt handling. The stacks are twelve levels deep to allow interrupt, loop and subroutine nesting.

The following instructions allow global enable or disable servicing of the interrupts (including power down), regardless of the state of IMASK. Disabling the interrupts does not affect serial port autobuffering or DMA.

*ENA INTS;*  
*DIS INTS;*

When the processor is reset, interrupt servicing is enabled.

**LOW POWER OPERATION**

The ADSP-2183 has three low power modes that significantly reduce the power dissipation when the device operates under standby conditions. These modes are:

- Power-Down
- Idle
- Slow Idle

The CLKOUT pin may also be disabled to reduce external power dissipation.

**Power-Down**

The ADSP-2183 processor has a low power feature that lets the processor enter a very low power dormant state through hardware or software control. Here is a brief list of power-down features. Refer to the *ADSP-2100 Family User's Manual*, Third Edition, "System Interface" chapter for detailed information about the power-down feature.

- Quick recovery from power-down. The processor begins executing instructions in as few as 300 CLKIN cycles.
- Support for an externally generated TTL or CMOS processor clock. The external clock can continue running during power-down without affecting the lowest power rating and 300 CLKIN cycle recovery.
- Support for crystal operation includes disabling the oscillator to save power (the processor automatically waits 4096 CLKIN cycles for the crystal oscillator to start and stabilize), and letting the oscillator run to allow 300 CLKIN cycle start-up.
- Power-down is initiated by either the power-down pin ( $\overline{PWD}$ ) or the software power-down force bit.
- Interrupt support allows an unlimited number of instructions to be executed before optionally powering down. The power-down interrupt also can be used as a non-maskable, edge-sensitive interrupt.
- Context clear/save control allows the processor to continue where it left off or start with a clean context when leaving the power-down state.
- The  $\overline{RESET}$  pin also can be used to terminate power-down.
- Power-down acknowledge pin indicates when the processor has entered power-down.

**Idle**

When the ADSP-2183 is in the Idle Mode, the processor waits indefinitely in a low power state until an interrupt occurs. When an unmasked interrupt occurs, it is serviced; execution then continues with the instruction following the *IDLE* instruction.

**Slow Idle**

The *IDLE* instruction is enhanced on the ADSP-2183 to let the processor's internal clock signal be slowed, further reducing power consumption. The reduced clock frequency, a programmable fraction of the normal clock rate, is specified by a selectable divisor given in the *IDLE* instruction. The format of the instruction is

$$IDLE (n);$$

where  $n = 16, 32, 64$  or  $128$ . This instruction keeps the processor fully functional, but operating at the slower clock rate. While it is in this state, the processor's other internal clock signals, such as SCLK, CLKOUT and timer clock, are reduced by the same ratio. The default form of the instruction, when no clock divisor is given, is the standard *IDLE* instruction.

# ADSP-2183

When the *IDLE (n)* instruction is used, it effectively slows down the processor's internal clock, and thus its response time, to incoming interrupts. The one-cycle response time of the standard idle state is increased by *n*, the clock divisor. When an enabled interrupt is received, the ADSP-2183 will remain in the idle state for up to a maximum of *n* processor cycles (*n* = 16, 32, 64 or 128) before resuming normal operation.

When the *IDLE (n)* instruction is used in systems with an externally generated serial clock (SCLK), the serial clock rate may be faster than the processor's reduced internal clock rate. Under these conditions, interrupts must not be generated at a faster rate than can be serviced, due to the additional time the processor takes to come out of the idle state (a maximum of *n* processor cycles).

## SYSTEM INTERFACE

Figure 2 shows a typical basic system configuration with the ADSP-2183, two serial devices, a byte-wide EPROM and optional external program and data overlay memories. Programmable wait state generation allows the processor to connect easily to slow peripheral devices. The ADSP-2183 also provides four external interrupts and two serial ports or six external interrupts and one serial port.

Figure 2. ADSP-2183 Basic System Configuration

### Clock Signals

The ADSP-2183 can be clocked by either a crystal or a TTL-compatible clock signal.

The CLKIN input cannot be halted, changed during operation or operated below the specified frequency during normal operation. The only exception is while the processor is in the power-down state. For additional information, refer to Chapter 9, *ADSP-2100 Family User's Manual*, Third Edition, for detailed information on this power-down feature.

If an external clock is used, it should be a TTL-compatible signal running at half the instruction rate. The signal is connected to the processor's CLKIN input. When an external clock is used, the XTAL input *must* be left unconnected.

The ADSP-2183 uses an input clock with a frequency equal to half the instruction rate; a 16.67 MHz input clock yields a 30 ns processor cycle (which is equivalent to 33 MHz). Normally, instructions are executed in a single processor cycle. All device timing is relative to the internal instruction clock rate, which is indicated by the CLKOUT signal when enabled.

Because the ADSP-2183 includes an on-chip oscillator circuit, an external crystal may be used. The crystal should be connected across the CLKIN and XTAL pins, with two capacitors connected as shown in Figure 3. Capacitor values are dependent on crystal type and should be specified by the crystal manufacturer. A parallel-resonant, fundamental frequency, microprocessor-grade crystal should be used.

A clock output (CLKOUT) signal is generated by the processor at the processor's cycle rate. This can be enabled and disabled by the CLKODIS bit in the SPORT0 Autobuffer Control Register.

Figure 3. External Crystal Connections

### Reset

The RESET signal initiates a master reset of the ADSP-2183. The RESET signal must be asserted during the power-up sequence to assure proper initialization. RESET during initial power-up must be held long enough to allow the internal clock to stabilize. If RESET is activated any time after power-up, the clock continues to run and does not require stabilization time.

The power-up sequence is defined as the total time required for the crystal oscillator circuit to stabilize after a valid  $V_{DD}$  is applied to the processor, and for the internal phase-locked loop (PLL) to lock onto the specific crystal frequency. A minimum of 2000 CLKIN cycles ensures that the PLL has locked, but does not include the crystal oscillator start-up time. During this power-up sequence the RESET signal should be held low. On any subsequent resets, the RESET signal must meet the minimum pulsewidth specification,  $t_{RSP}$ .

The RESET input contains some hysteresis; however, if you use an RC circuit to generate your RESET signal, the use of an external Schmidt trigger is recommended.

The master reset sets all internal stack pointers to the empty stack condition, masks all interrupts and clears the MSTAT register. When RESET is released, if there is no pending bus request and the chip is configured for booting (MMAP = 0), the boot-loading sequence is performed. The first instruction is fetched from on-chip program memory location 0x0000 once boot loading completes.

## Memory Architecture

The ADSP-2183 provides a variety of memory and peripheral interface options. The key functional groups are Program Memory, Data Memory, Byte Memory and I/O.

**Program Memory** is a 24-bit-wide space for storing both instruction opcodes and data. The ADSP-2183 has 16K words of Program Memory RAM on chip and the capability of accessing up to two 8K external memory overlay spaces using the external data bus. Both an instruction opcode and a data value can be read from on-chip program memory in a single cycle.

**Data Memory** is a 16-bit-wide space used for the storage of data variables and for memory-mapped control registers. The ADSP-2183 has 16K words on Data Memory RAM on chip, consisting of 16,352 user-accessible locations and 32 memory-mapped registers. Support also exists for up to two 8K external memory overlay spaces through the external data bus.

**Byte Memory** provides access to an 8-bit-wide memory space through the Byte DMA (BDMA) port. The Byte Memory interface provides access to 4 MBytes of memory by utilizing eight data lines as additional address lines. This gives the BDMA Port an effective 22-bit address range. On power-up, the DSP can automatically load bootstrap code from byte memory.

**I/O Space** allows access to 2048 locations of 16-bit-wide data. It is intended to be used to communicate with parallel peripheral devices such as data converters and external registers or latches.

### Program Memory

The ADSP-2183 contains a 16K × 24 on-chip program RAM. The on-chip program memory is designed to allow up to two accesses each cycle so that all operations can complete in a single cycle. In addition, the ADSP-2183 allows the use of 8K external memory overlays.

The program memory space organization is controlled by the MMAP pin and the PMOVLAY register. Normally, the ADSP-2183 is configured with MMAP = 0 and program memory organized as shown in Figure 4.

PROGRAM MEMORY	ADDRESS
8K INTERNAL (PMOVLAY = 0, MMAP = 0) OR EXTERNAL 8K (PMOVLAY = 1 or 2, MMAP = 0)	0x3FFF
	0x2000
8K INTERNAL	0x1FFF
	0x0000

Figure 4. Program Memory (MMAP = 0)

There are 16K words of memory accessible internally when the PMOVLAY register is set to 0. When PMOVLAY is set to something other than 0, external accesses occur at addresses 0x2000 through 0x3FFF. The external address is generated as shown in Table II.

Table II.

PMOVLAY	Memory	A13	A12:0
0	Internal	Not Applicable	Not Applicable
1	External Overlay 1	0	13 LSBs of Address Between 0x2000 and 0x3FFF
2	External Overlay 2	1	13 LSBs of Address Between 0x2000 and 0x3FFF

This organization provides for two external 8K overlay segments using only the normal 14 address bits. This allows for simple program overlays using one of the two external segments in place of the on-chip memory. Care must be taken in using this overlay space because the processor core (i.e., the sequencer) does not take the PMOVLAY register value into account. For example, if a loop operation were occurring on one of the external overlays, and the program changes to another external overlay or internal memory, an incorrect loop operation could occur. In addition, care must be taken in interrupt service routines as the overlay registers are not automatically saved and restored on the processor mode stack.

For ADSP-2100 Family compatibility, MMAP = 1 is allowed. In this mode, booting is disabled and overlay memory is disabled (PMOVLAY must be 0). Figure 5 shows the memory map in this configuration.

PROGRAM MEMORY	ADDRESS
INTERNAL 8K (PMOVLAY = 0, MMAP = 1)	0x3FFF
	0x2000
8K EXTERNAL	0x1FFF
	0x0000

Figure 5. Program Memory (MMAP = 1)

### Data Memory

The ADSP-2183 has 16,352 16-bit words of internal data memory. In addition, the ADSP-2183 allows the use of 8K external memory overlays. Figure 6 shows the organization of the data memory.

DATA MEMORY	ADDRESS
32 MEMORY-MAPPED REGISTERS	0x3FFF
	0x3FEO

	0x0000

Figure 6. Data Memory

# ADSP-2183

There are 16,352 words of memory accessible internally when the DMOVLAY register is set to 0. When DMOVLAY is set to something other than 0, external accesses occur at addresses 0x0000 through 0x1FFF. The external address is generated as shown in Table III.

**Table III.**

DMOVLAY	Memory	A13	A12:0
0	Internal	Not Applicable	Not Applicable
1	External Overlay 1	0	13 LSBs of Address Between 0x0000 and 0x1FFF
2	External Overlay 2	1	13 LSBs of Address Between 0x0000 and 0x1FFF

This organization allows for two external 8K overlays using only the normal 14 address bits.

All internal accesses complete in one cycle. Accesses to external memory are timed using the wait states specified by the DWAIT register.

### I/O Space

The ADSP-2183 supports an additional external memory space called I/O space. This space is designed to support simple connections to peripherals or to bus interface ASIC data registers. I/O space supports 2048 locations. The lower eleven bits of the external address bus are used; the upper 3 bits are undefined. Two instructions were added to the core ADSP-2100 Family instruction set to read from and write to I/O memory space. The I/O space also has four dedicated 3-bit wait state registers, IOWAIT0-3, which specify up to seven wait states to be automatically generated for each of four regions. The wait states act on address ranges as shown in Table IV.

**Table IV.**

Address Range	Wait State Register
0x000-0x1FF	IOWAIT0
0x200-0x3FF	IOWAIT1
0x400-0x5FF	IOWAIT2
0x600-0x7FF	IOWAIT3

### Composite Memory Select ( $\overline{\text{CMS}}$ )

The ADSP-2183 has a programmable memory select signal that is useful for generating memory select signals for memories mapped to more than one space. The  $\overline{\text{CMS}}$  signal is generated to have the same timing as each of the individual memory select signals ( $\overline{\text{PMS}}$ ,  $\overline{\text{DMS}}$ ,  $\overline{\text{BMS}}$ ,  $\overline{\text{IOMS}}$ ) but can combine their functionality.

When set, each bit in the CMSSEL register causes the  $\overline{\text{CMS}}$  signal to be asserted when the selected memory select is asserted. For example, to use a 32K word memory to act as both program and data memory, set the PMS and DMS bits in the CMSSEL register and use the  $\overline{\text{CMS}}$  pin to drive the chip select of the memory; use either  $\overline{\text{DMS}}$  or  $\overline{\text{PMS}}$  as the additional address bit.

The  $\overline{\text{CMS}}$  pin functions like the other memory select signals, with the same timing and bus request logic. A 1 in the enable bit causes the assertion of the  $\overline{\text{CMS}}$  signal at the same time as the selected memory select signal. All enable bits, except the  $\overline{\text{BMS}}$  bit, default to 1 at reset.

### Byte Memory

The byte memory space is a bidirectional, 8-bit-wide, external memory space used to store programs and data. Byte memory is accessed using the BDMA feature. The byte memory space consists of 256 pages, each of which is 16K × 8.

The byte memory space on the ADSP-2183 supports read and write operations as well as four different data formats. The byte memory uses data bits 15:8 for data. The byte memory uses data bits 23:16 and address bits 13:0 to create a 22-bit address. This allows up to a 4 meg × 8 (32 megabit) ROM or RAM to be used without glue logic. All byte memory accesses are timed by the BMWAIT register.

### Byte Memory DMA (BDMA)

The Byte memory DMA controller allows loading and storing of program instructions and data using the byte memory space. The BDMA circuit is able to access the byte memory space, while the processor is operating normally and steals only one DSP cycle per 8-, 16- or 24-bit word transferred.

The BDMA circuit supports four different data formats which are selected by the BTYPE register field. The appropriate number of 8-bit accesses are done from the byte memory space to build the word size selected. Table V shows the data formats supported by the BDMA circuit.

**Table V.**

BTYPE	Internal Memory Space	Word Size	Alignment
00	Program Memory	24	Full Word
01	Data Memory	16	Full Word
10	Data Memory	8	MSBs
11	Data Memory	8	LSBs

Unused bits in the 8-bit data memory formats are filled with 0s. The BIAD register field is used to specify the starting address for the on-chip memory involved with the transfer. The 14-bit BEAD register specifies the starting address for the external byte memory space. The 8-bit BMPAGE register specifies the starting page for the external byte memory space. The BDIR register field selects the direction of the transfer. Finally the 14-bit BWCOUNT register specifies the number of DSP words to transfer and initiates the BDMA circuit transfers.

BDMA accesses can cross page boundaries during sequential addressing. A BDMA interrupt is generated on the completion of the number of transfers specified by the BWCOUNT register. The BWCOUNT register is updated after each transfer so it can be used to check the status of the transfers. When it reaches zero, the transfers have finished and a BDMA interrupt is generated. The BMPAGE and BEAD registers must not be accessed by the DSP during BDMA operations.

The source or destination of a BDMA transfer will always be on-chip program or data memory, regardless of the values of MMAP, PMOVLAY or DMOVLAY.

# ADSP-2183

If Go Mode is enabled, the ADSP-2183 will not halt program execution until it encounters an instruction that requires an external memory access.

If the ADSP-2183 is performing an external memory access when the external device asserts the  $\overline{BR}$  signal, then it will not three-state the memory interfaces or assert the  $\overline{BG}$  signal until the processor cycle after the access completes. The instruction does not need to be completed when the bus is granted. If a single instruction requires two external memory accesses, the bus will be granted between the two accesses.

When the  $\overline{BR}$  signal is released, the processor releases the  $\overline{BG}$  signal, reenables the output drivers and continues program execution from the point where it stopped.

The bus request feature operates at all times, including when the processor is booting and when  $\overline{RESET}$  is active.

The  $\overline{BGH}$  pin is asserted when the ADSP-2183 is ready to execute an instruction, but is stopped because the external bus is already granted to another device. The other device can release the bus by deasserting bus request. Once the bus is released, the ADSP-2183 deasserts  $\overline{BG}$  and  $\overline{BGH}$  and executes the external memory access.

## Flag I/O Pins

The ADSP-2183 has eight general purpose programmable input/output flag pins. They are controlled by two memory mapped registers. The PFTYPE register determines the direction, 1 = output and 0 = input. The PFDATA register is used to read and write the values on the pins. Data being read from a pin configured as an input is synchronized to the ADSP-2183's clock. Bits that are programmed as outputs will read the value being output. The PF pins default to input during reset.

In addition to the programmable flags, the ADSP-2183 has five fixed-mode flags, FLAG\_IN, FLAG\_OUT, FL0, FL1 and FL2. FL0-FL2 are dedicated output flags. FLAG\_IN and FLAG\_OUT are available as an alternate configuration of SPORT1.

## INSTRUCTION SET DESCRIPTION

The ADSP-2183 assembly language instruction set has an algebraic syntax that was designed for ease of coding and readability. The assembly language, which takes full advantage of the processor's unique architecture, offers the following benefits:

- The algebraic syntax eliminates the need to remember cryptic assembler mnemonics. For example, a typical arithmetic add instruction, such as  $AR = AX0 + AY0$ , resembles a simple equation.
- Every instruction assembles into a single, 24-bit word that can execute in a single instruction cycle.

- The syntax is a superset ADSP-2100 Family assembly language and is completely source and object code compatible with other family members. Programs may need to be relocated to utilize on-chip memory and conform to the ADSP-2183's interrupt vector and reset vector map.
- Sixteen condition codes are available. For conditional jump, call, return or arithmetic instructions, the condition can be checked and the operation executed in the same instruction cycle.
- Multifunction instructions allow parallel execution of an arithmetic instruction with up to two fetches or one write to processor memory space during a single instruction cycle.

## DESIGNING AN EZ-ICE-COMPATIBLE SYSTEM

The ADSP-2183 has on-chip emulation support and an ICE-Port, a special set of pins that interface to the EZ-ICE. These features allow in-circuit emulation without replacing the target system processor by using only a 14-pin connection from the target system to the EZ-ICE. Target systems must have a 14-pin connector to accept the EZ-ICE's in-circuit probe, a 14-pin plug.

The ICE-Port interface consists of the following ADSP-2183 pins:

$\overline{EBR}$	$\overline{EBG}$	$\overline{ERESET}$
EMS	EINT	ECLK
ELIN	ELOUT	EE

These ADSP-2183 pins must be connected *only* to the EZ-ICE connector in the target system. These pins have no function except during emulation, and do not require pull-up or pull-down resistors. The traces for these signals between the ADSP-2183 and the connector must be kept as short as possible, no longer than three inches.

The following pins are also used by the EZ-ICE:

$\overline{BR}$	$\overline{BG}$
$\overline{RESET}$	GND

The EZ-ICE uses the EE (emulator enable) signal to take control of the ADSP-2183 in the target system. This causes the processor to use its  $\overline{ERESET}$ ,  $\overline{EBR}$  and  $\overline{EBG}$  pins instead of the  $\overline{RESET}$ ,  $\overline{BR}$  and  $\overline{BG}$  pins. The  $\overline{BG}$  output is three-stated. These signals do not need to be jumper-isolated in your system.

The EZ-ICE connects to your target system via a ribbon cable and a 14-pin female plug. The ribbon cable is 10 inches in length with one end fixed to the EZ-ICE. The female plug is plugged onto the 14-pin connector (a pin strip header) on the target board.

### Target Board Connector for EZ-ICE Probe

The EZ-ICE connector (a standard pin strip header) is shown in Figure 7. You must add this connector to your target board design if you intend to use the EZ-ICE. Be sure to allow enough room in your system to fit the EZ-ICE probe onto the 14-pin connector.

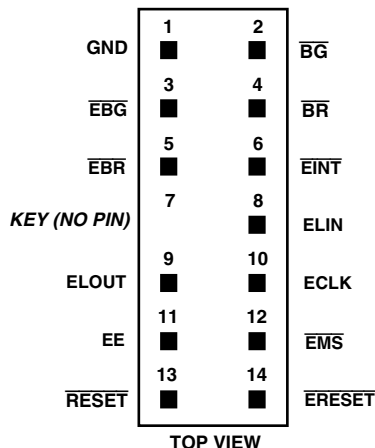

Figure 7. Target Board Connector for EZ-ICE

The 14-pin, 2-row pin strip header is keyed at the Pin 7 location—you must remove Pin 7 from the header. The pins must be 0.025 inch square and at least 0.20 inch in length. Pin spacing should be 0.1 × 0.1 inches. The pin strip header must have at least 0.15 inch clearance on all sides to accept the EZ-ICE probe plug. Pin strip headers are available from vendors such as 3M, McKenzie, and Samtec.

### Target Memory Interface

For your target system to be compatible with the EZ-ICE emulator, it must comply with the memory interface guidelines listed below.

#### PM, DM, BM, IOM and CM

Design your Program Memory (PM), Data Memory (DM), Byte Memory (BM), I/O Memory (IOM), and Composite Memory (CM) external interfaces to comply with worst case device timing requirements and switching characteristics as specified in the DSP's data sheet. The performance of the EZ-ICE may approach published worst case specification for some memory access timing requirements and switching characteristics.

**Note:** If your target does not meet the worst case chip specification for memory access parameters, you may not be able to emulate your circuitry at the desired CLKIN frequency. Depending on the severity of the specification violation, you may have trouble manufacturing your system as DSP components statistically vary in switching characteristic and timing requirements within published limits.

**Restriction:** All memory strobe signals on the ADSP-2183 ( $\overline{RD}$ ,  $\overline{WR}$ , PMS, DMS, BMS, CMS and IOMS) used in your target system must have 10 k $\Omega$  pull-up resistors connected when the EZ-ICE is being used. The pull-up resistors are necessary because there are no internal pull-ups to guarantee their state during prolonged three-state conditions resulting from typical EZ-ICE debugging sessions. These resistors may be removed at your option when the EZ-ICE is not being used.

### Target System Interface Signals

When the EZ-ICE board is installed, the performance on some system signals changes. Design your system to be compatible with the following system interface signal changes introduced by the EZ-ICE board:

- EZ-ICE emulation introduces an 8 ns propagation delay between your target circuitry and the DSP on the  $\overline{RESET}$  signal.
- EZ-ICE emulation introduces an 8 ns propagation delay between your target circuitry and the DSP on the  $\overline{BR}$  signal.
- EZ-ICE emulation ignores  $\overline{RESET}$  and  $\overline{BR}$  when single-stepping.
- EZ-ICE emulation ignores  $\overline{RESET}$  and  $\overline{BR}$  when in Emulator Space (DSP halted).
- EZ-ICE emulation ignores the state of target  $\overline{BR}$  in certain modes. As a result, the target system may take control of the DSP's external memory bus *only* if bus grant ( $\overline{BG}$ ) is asserted by the EZ-ICE board's DSP.

### Target Architecture File

The EZ-ICE software lets you load your program in its linked (executable) form. The EZ-ICE PC program can not load sections of your executable located in boot pages (by the linker). With the exception of boot page 0 (loaded into PM RAM), all sections of your executable mapped into boot pages are not loaded.

Write your target architecture file to indicate that only PM RAM is available for *program storage*, when using the EZ-ICE software's loading feature. Data can be loaded to PM RAM or DM RAM.

## OUTPUT DRIVE CURRENTS

Figure 19 shows typical I-V characteristics for the output drivers of the ADSP-2183. The curves represent the current drive capability of the output drivers as a function of output voltage.

Figure 19. Typical Drive Currents

- NOTES:
1. REFLECTS ADSP-2183 OPERATION IN LOWEST POWER MODE. (SEE "SYSTEM INTERFACE" CHAPTER OF THE ADSP-2100 FAMILY USER'S MANUAL FOR DETAILS.)
  2. CURRENT REFLECTS DEVICE OPERATING WITH NO INPUT LOADS.

Figure 20. Power-Down Supply Current (Typical)

## POWER DISSIPATION

To determine total power dissipation in a specific application, the following equation should be applied for each output:

$$C \times V_{DD}^2 \times f$$

$C$  = load capacitance,  $f$  = output switching frequency.

### Example:

In an application where external data memory is used and no other outputs are active, power dissipation is calculated as follows:

Assumptions:

- External data memory is accessed every cycle with 50% of the address pins switching.
- External data memory writes occur every other cycle with 50% of the data pins switching.
- Each address and data pin has a 10 pF total load at the pin.
- The application operates at  $V_{DD} = 3.3$  V and  $t_{CK} = 30.0$  ns.

$$\text{Total Power Dissipation} = P_{INT} + (C \times V_{DD}^2 \times f)$$

$P_{INT}$  = internal power dissipation from Power vs. Frequency graph (Figure 20).

$(C \times V_{DD}^2 \times f)$  is calculated for each output:

	# of Pins	$\times C$	$\times V_{DD}^2$	$\times f$	
Address, $\overline{DMS}$	8	$\times 10$ pF	$\times 3.3^2$ V	$\times 33.3$ MHz	= 29.0 mW
Data Output, $\overline{WR}$	9	$\times 10$ pF	$\times 3.3^2$ V	$\times 16.67$ MHz	= 16.3 mW
$\overline{RD}$	1	$\times 10$ pF	$\times 3.3^2$ V	$\times 16.67$ MHz	= 1.8 mW
CLKOUT	1	$\times 10$ pF	$\times 3.3^2$ V	$\times 33.3$ MHz	= 3.6 mW
					<u>50.7 mW</u>

Total power dissipation for this example is  $P_{INT} + 50.7$  mW.

- VALID FOR ALL TEMPERATURE GRADES.
- <sup>1</sup>POWER REFLECTS DEVICE OPERATING WITH NO OUTPUT LOADS.
  - <sup>2</sup>IDLE REFERS TO ADSP-2183 STATE OF OPERATION DURING EXECUTION OF IDLE INSTRUCTION. DEASSERTED PINS ARE DRIVEN TO EITHER  $V_{DD}$  OR GND.
  - <sup>3</sup>TYPICAL POWER DISSIPATION AT 3.3V  $V_{DD}$  AND 25°C EXCEPT WHERE SPECIFIED.
  - <sup>4</sup> $I_{DD}$  MEASUREMENT TAKEN WITH ALL INSTRUCTIONS EXECUTING FROM INTERNAL MEMORY. 50% OF THE INSTRUCTIONS ARE MULTIFUNCTION (TYPES 1,4,5,12,13,14), 30% ARE TYPE 2 AND TYPE 6, AND 20% ARE IDLE INSTRUCTIONS.
