Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

General Guideline

Maximum performance numbers in this datasheet are based on characterized data. Actel does not guarantee performance beyond the limits specified within the datasheet.

ProASIC^PLUS Architecture

The proprietary ProASIC^PLUS architecture provides granularity comparable to gate arrays.

The ProASIC^PLUS device core consists of a Sea-of-Tiles (Figure 1-1). Each tile can be configured as a three-input logic function (e.g., NAND gate, D-Flip-Flop, etc.) by programming the appropriate Flash switch interconnections (Figure 1-2 and Figure 1-3 on page 1-3). Tiles and larger functions are connected with any of the four levels of routing hierarchy. Flash switches are distributed throughout the device to provide nonvolatile, reconfigurable interconnect programming. Flash switches are programmed to connect signal lines to the appropriate logic cell inputs and outputs. Dedicated high-performance lines are connected as needed for fast, low-skew global signal distribution throughout the core. Maximum core utilization is possible for virtually any design.

ProASIC^PLUS devices also contain embedded, two-port SRAM blocks with built-in FIFO/RAM control logic. Programming options include synchronous or asynchronous operation, two-port RAM configurations, user defined depth and width, and parity generation or checking. Please see the "Embedded Memory Configurations" section on page 1-23 for more information.

Logic Tile Timing Characteristics

Timing characteristics for ProASIC^PLUS devices fall into three categories: family dependent, device dependent, and design dependent. The input and output buffer characteristics are common to all ProASIC^PLUS family members. Internal routing delays are device dependent. Design dependency means that actual delays are not determined until after placement and routing of the user's design are complete. Delay values may then be determined by using the Timer utility or by performing simulation with post-layout delays.

Critical Nets and Typical Nets

Propagation delays are expressed only for typical nets, which are used for initial design performance evaluation. Critical net delays can then be applied to the most timing-critical paths. Critical nets are determined by net property assignment prior to place-and-route. Refer to the Actel *Designer User's Guide* or online help for details on using constraints.

Timing Derating

Since ProASIC^PLUS devices are manufactured with a CMOS process, device performance will vary with temperature, voltage, and process. Minimum timing parameters reflect maximum operating voltage, minimum operating temperature, and optimal process variations. Maximum timing parameters reflect minimum operating voltage, maximum operating temperature, and worst-case process variations (within process specifications). The derating factors shown in Table 1-9 should be applied to all timing data contained within this datasheet.

All timing numbers listed in this datasheet represent sample timing characteristics of ProASIC^PLUS devices. Actual timing delay values are design-specific and can be derived from the Timer tool in Actel's Designer software after place-and-route.

Table 1-9 • **Temperature and Voltage Derating Factors (Normalized to Worst-Case Commercial, T_J = 70°C, V_{DD} = 2.3 V)**

	–55°C	–40°C	0°C	25°C	70°C	85°C	110°C	125°C	135°C	150°C

Notes:

1. *The user can set the junction temperature in Designer software to be any integer value in the range of –55°C to 175°C.*
2. *The user can set the core voltage in Designer software to be any value between 1.4 V and 1.6 V.*

User Security

ProASIC^PLUS devices have FlashLock protection bits that, once programmed, block the entire programmed contents from being read externally. Please refer to Table 1-11 for details on the number of bits in the key for each device. If locked, the user can only reprogram the device employing the user-defined security key. This protects the device from being read back and duplicated. Since programmed data is stored in nonvolatile memory cells (actually very small capacitors) rather than in the wiring, physical deconstruction cannot be used to compromise data. This type of security breach is further discouraged by the placement of the memory cells beneath the four metal layers (whose removal cannot be accomplished without disturbing the charge in the capacitor). This is the highest security provided in the industry. For more information, refer to Actel's *Design Security in Nonvolatile Flash and Antifuse FPGAs* white paper.

Embedded Memory Floorplan

The embedded memory is located across the top and bottom of the device in 256x9 blocks (Figure 1-1 on page 1-2). Depending on the device, up to 88 blocks are available to support a variety of memory configurations. Each block can be programmed as an independent memory array or combined (using dedicated memory routing resources) to form larger, more complex memory configurations. A single memory configuration could include blocks from both the top and bottom memory locations.

Embedded Memory Configurations

The embedded memory in the ProASIC^PLUS family provides great configuration flexibility (Table 1-12). Each ProASIC^PLUS block is designed and optimized as a two-port memory (one read, one write). This provides 198 kbits of two-port and/or single port memory in the APA1000 device.

Each memory block can be configured as FIFO or SRAM, with independent selection of synchronous or asynchronous read and write ports (Table 1-13). Additional characteristics include programmable flags as well as parity checking and generation. Figure 1-21 on page 1-25 and Figure 1-22 on page 1-26 show the block diagrams of the basic SRAM and FIFO blocks. Table 1-14 on page 1-25 and Table 1-15 on page 1-26 describe memory block SRAM and FIFO interface signals, respectively. A single memory block is designed to operate at up to 150 MHz (standard speed grade typical conditions). Each block is comprised of 256 9-bit words (one read port, one write port). The memory blocks may be cascaded in width and/or depth to create the desired memory organization. (Figure 1-23 on page 1-27). This provides optimal bit widths of 9 (one block), 18, 36, and 72, and optimal depths of 256, 512, 768, and 1,024. Refer to Actel's *SmartGen User's Guide* for more information.

Figure 1-24 on page 1-27 gives an example of optimal memory usage. Ten blocks with 23,040 bits have been used to generate three arrays of various widths and depths. Figure 1-25 on page 1-27 shows how RAM blocks can be used in parallel to create extra read ports. In this example, using only 10 of the 88 available blocks of the APA1000 yields an effective 6,912 bits of multiple port RAM. The Actel SmartGen software facilitates building wider and deeper memory configurations for optimal memory usage.

Package Thermal Characteristics

The ProASIC^PLUS family is available in several package types with a range of pin counts. Actel has selected packages based on high pin count, reliability factors, and superior thermal characteristics.

Thermal resistance defines the ability of a package to conduct heat away from the silicon, through the package to the surrounding air. Junction-to-ambient thermal resistance is measured in degrees Celsius/Watt and is represented as Theta ja (Θ_{ja}). The lower the thermal resistance, the more efficiently a package will dissipate heat.

A package's maximum allowed power (P) is a function of maximum junction temperature (T_J), maximum ambient operating temperature (T_A), and junction-to-ambient thermal resistance Θ_{ja}. Maximum junction temperature is the maximum allowable temperature on the active surface of the IC and is 110° C. P is defined as:

$$P = \frac{T_J - T_A}{\Theta_{ja}}$$

EQ 1-4

Θ_{ja} is a function of the rate (in linear feet per minute (lfpm)) of airflow in contact with the package. When the estimated power consumption exceeds the maximum allowed power, other means of cooling, such as increasing the airflow rate, must be used. The maximum power dissipation allowed for a Military temperature device is specified as a function of Θ_{jc}. The absolute maximum junction temperature is 150°C.

The calculation of the absolute maximum power dissipation allowed for a Military temperature application is illustrated in the following example for a 456-pin PBGA package:

$$\text{Maximum Power Allowed} = \frac{\text{Max. junction temp. (°C)} - \text{Max. case temp. (°C)}}{\theta_{jc}(\text{°C/W})} = \frac{150\text{°C} - 125\text{°C}}{3.0\text{°C/W}} = 8.333\text{W}$$

Performance Retention

For devices operated and stored at 110°C or less, the performance retention period is 20 years after programming. For devices operated and stored at temperatures greater than 110°C, refer to Table 1-19 on page 1-35 to determine the performance retention period. Actel does not guarantee performance if the performance retention period is exceeded. Designers can determine the performance retention period from the following table.

Evaluate the percentage of time spent at the highest temperature, then determine the next highest temperature to which the device will be exposed. In Table 1-19 on page 1-35, find the temperature profile that most closely matches the application.

Example – the ambient temperature of a system cycles between 100°C (25% of the time) and 50°C (75% of the time). No forced ventilation cooling system is in use. An APA600-PQ208M FPGA operates in the system, dissipating 1 W. The package thermal resistance (junction-to-ambient) in still air Θ_{ja} is 20°C/W, indicating that the junction temperature of the FPGA will be 120°C (25% of the time) and 70°C (75% of the time). The entry in Table 1-19 on page 1-35, which most closely matches the application, is 25% at 125°C with 75% at 110°C. Performance retention in this example is at least 16.0 years.

Note that exceeding the stated retention period may result in a performance degradation in the FPGA below the worst-case performance indicated in the Actel Timer. To ensure that performance does not degrade below the worst-case values in the Actel Timer, the FPGA must be reprogrammed within the performance retention period. In addition, note that performance retention is independent of whether or not the FPGA is operating. The retention period of a device in storage at a given temperature will be the same as the retention period of a device operating at that junction temperature.
