
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Obsolete
Core Processor	XA
Core Size	16-Bit
Speed	30MHz
Connectivity	UART/USART
Peripherals	PWM, WDT
Number of I/O	32
Program Memory Size	-
Program Memory Type	ROMless
EEPROM Size	-
RAM Size	512 x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 5.5V
Data Converters	-
Oscillator Type	External
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	44-LCC (J-Lead)
Supplier Device Package	44-PLCC (16.59x16.59)
Purchase URL	https://www.e-xfl.com/product-detail/nxp-semiconductors/pxag30kfa-529

PIN DESCRIPTIONS

MNEMONIC	PIN. NO.		TYPE	NAME AND FUNCTION
	PLCC	LQFP		
V_{SS}	1, 22	16	I	**Ground:** 0 V reference.
V_{DD}	23, 44	17	I	**Power Supply:** This is the power supply voltage for normal, idle, and power down operation.
P0.0 – P0.7	43–36	37–30	I/O	**Port 0:** Port 0 is an 8-bit I/O port with a user-configurable output type. Port 0 latches have 1s written to them and are configured in the quasi-bidirectional mode during reset. The operation of port 0 pins as inputs and outputs depends upon the port configuration selected. Each port pin is configured independently. Refer to the section on I/O port configuration and the DC Electrical Characteristics for details. When the external program/data bus is used, Port 0 becomes the multiplexed low data/instruction byte and address lines 4 through 11.
P1.0 – P1.7	2–9	40–44, 1–3	I/O	**Port 1:** Port 1 is an 8-bit I/O port with a user-configurable output type. Port 1 latches have 1s written to them and are configured in the quasi-bidirectional mode during reset. The operation of port 1 pins as inputs and outputs depends upon the port configuration selected. Each port pin is configured independently. Refer to the section on I/O port configuration and the DC Electrical Characteristics for details. Port 1 also provides special functions as described below.
	2	40	O	**A0/$\overline{\text{WRH}}$:** Address bit 0 of the external address bus when the external data bus is configured for an 8 bit width. When the external data bus is configured for a 16 bit width, this pin becomes the high byte write strobe.
	3	41	O	**A1:** Address bit 1 of the external address bus.
	4	42	O	**A2:** Address bit 2 of the external address bus.
	5	43	O	**A3:** Address bit 3 of the external address bus.
	6	44	I	**RxD1 (P1.4):** Receiver input for serial port 1.
	7	1	O	**TxD1 (P1.5):** Transmitter output for serial port 1.
	8	2	I/O	**T2 (P1.6):** Timer/counter 2 external count input/clockout.
	9	3	I	**T2EX (P1.7):** Timer/counter 2 reload/capture/direction control
P2.0 – P2.7	24–31	18–25	I/O	**Port 2:** Port 2 is an 8-bit I/O port with a user-configurable output type. Port 2 latches have 1s written to them and are configured in the quasi-bidirectional mode during reset. The operation of port 2 pins as inputs and outputs depends upon the port configuration selected. Each port pin is configured independently. Refer to the section on I/O port configuration and the DC Electrical Characteristics for details. When the external program/data bus is used in 16-bit mode, Port 2 becomes the multiplexed high data/instruction byte and address lines 12 through 19. When the external program/data bus is used in 8-bit mode, the number of address lines that appear on port 2 is user programmable.
P3.0 – P3.7	11, 13–19	5, 7–13	I/O	**Port 3:** Port 3 is an 8-bit I/O port with a user configurable output type. Port 3 latches have 1s written to them and are configured in the quasi-bidirectional mode during reset. the operation of port 3 pins as inputs and outputs depends upon the port configuration selected. Each port pin is configured independently. Refer to the section on I/O port configuration and the DC Electrical Characteristics for details. Port 3 also provides various special functions as described below.
	11	5	I	**RxD0 (P3.0):** Receiver input for serial port 0.
	13	7	O	**TxD0 (P3.1):** Transmitter output for serial port 0.
	14	8	I	**$\overline{\text{INT0}}$ (P3.2):** External interrupt 0 input.
	15	9	I	**$\overline{\text{INT1}}$ (P3.3):** External interrupt 1 input.
	16	10	I/O	**T0 (P3.4):** Timer 0 external input, or timer 0 overflow output.
	17	11	I/O	**T1/BUSW (P3.5):** Timer 1 external input, or timer 1 overflow output. The value on this pin is latched as the external reset input is released and defines the default external data bus width (BUSW). 0 = 8-bit bus and 1 = 16-bit bus.
	18	12	O	**$\overline{\text{WRL}}$ (P3.6):** External data memory low byte write strobe.
	19	13	O	**$\overline{\text{RD}}$ (P3.7):** External data memory read strobe.
$\overline{\text{RST}}$	10	4	I	**Reset:** A low on this pin resets the microcontroller, causing I/O ports and peripherals to take on their default states, and the processor to begin execution at the address contained in the reset vector. Refer to the section on Reset for details.
ALE/$\overline{\text{PROG}}$	33	27	I/O	**Address Latch Enable/Program Pulse:** A high output on the ALE pin signals external circuitry to latch the address portion of the multiplexed address/data bus. A pulse on ALE occurs only when it is needed in order to process a bus cycle.

NOTES:

* SFRs are bit addressable.

1. At reset, the BCR register is loaded with the binary value 0000 0a11, where “a” is the value on the BUSW pin. This defaults the address bus size to 20 bits since the XA-G30 has only 20 address lines.
2. SFR is loaded from the reset vector.
3. All bits except F1, F0, and P are loaded from the reset vector. Those bits are all 0.
4. Unimplemented bits in SFRs are X (unknown) at all times. Ones should not be written to these bits since they may be used for other purposes in future XA derivatives. The reset value shown for these bits is 0.
5. Port configurations default to quasi-bidirectional when the XA begins execution from internal code memory after reset, based on the condition found on the EA pin. Thus all PnCFGA registers will contain FF and PnCFGB registers will contain 00. When the XA begins execution using external code memory, the default configuration for pins that are associated with the external bus will be push-pull. The PnCFGA and PnCFGB register contents will reflect this difference.
6. The WDCON reset value is E6 for a Watchdog reset, E4 for all other reset causes.
7. The XA-G30 implements an 8-bit SFR bus, as stated in Chapter 8 of the *XA User Guide*. All SFR accesses must be 8-bit operations. Attempts to write 16 bits to an SFR will actually write only the lower 8 bits. Sixteen bit SFR reads will return undefined data in the upper byte.

New Enhanced Mode 0

For timers T0 or T1 the 13-bit count mode on the 80C51 (current Mode 0) has been replaced in the XA with a 16-bit auto-reload mode. Four additional 8-bit data registers (two per timer: RTHn and RTLn) are created to hold the auto-reload values. In this mode, the TH overflow will set the TF flag in the TCON register and cause both the TL and TH counters to be loaded from the RTL and RTH registers respectively.

These new SFRs will also be used to hold the TL reload data in the 8-bit auto-reload mode (Mode 2) instead of TH.

The overflow rate for Timer 0 or Timer 1 in Mode 0 may be calculated as follows:

Timer_Rate = Osc / (N * (65536 – Timer_Reload_Value))

where N = the TCLK prescaler value: 4 (default), 16, or 64.

Mode 1

Mode 1 is the 16-bit non-auto reload mode.

Mode 2

Mode 2 configures the Timer register as an 8-bit Counter (TLn) with automatic reload. Overflow from TLn not only sets TFn, but also reloads TLn with the contents of RTLn, which is preset by software. The reload leaves THn unchanged.

Mode 2 operation is the same for Timer/Counter 0.

The overflow rate for Timer 0 or Timer 1 in Mode 2 may be calculated as follows:

Timer_Rate = Osc / (N * (256 – Timer_Reload_Value))

where N = the TCLK prescaler value: 4, 16, or 64.

Mode 3

Timer 1 in Mode 3 simply holds its count. The effect is the same as setting TR1 = 0.

Timer 0 in Mode 3 establishes TL0 and TH0 as two separate counters. TL0 uses the Timer 0 control bits: C/T, GATE, TR0, INT0, and TF0. TH0 is locked into a timer function and takes over the use of TR1 and TF1 from Timer 1. Thus, TH0 now controls the “Timer 1” interrupt.

Mode 3 is provided for applications requiring an extra 8-bit timer. When Timer 0 is in Mode 3, Timer 1 can be turned on and off by switching it out of and into its own Mode 3, or can still be used by the serial port as a baud rate generator, or in fact, in any application not requiring an interrupt.

TCON Address:410
Bit Addressable
Reset Value: 00H

MSB							LSB
TF1	TR1	TF0	TR0	IE1	IT1	IE0	IT0

BIT	SYMBOL	FUNCTION
TCON.7	TF1	Timer 1 overflow flag. Set by hardware on Timer/Counter overflow. This flag will not be set if T1OE (TSTAT.2) is set. Cleared by hardware when processor vectors to interrupt routine, or by clearing the bit in software.
TCON.6	TR1	Timer 1 Run control bit. Set/cleared by software to turn Timer/Counter 1 on/off.
TCON.5	TF0	Timer 0 overflow flag. Set by hardware on Timer/Counter overflow. This flag will not be set if T0OE (TSTAT.0) is set. Cleared by hardware when processor vectors to interrupt routine, or by clearing the bit in software.
TCON.4	TR0	Timer 0 Run control bit. Set/cleared by software to turn Timer/Counter 0 on/off.
TCON.3	IE1	Interrupt 1 Edge flag. Set by hardware when external interrupt edge detected. Cleared when interrupt processed.
TCON.2	IT1	Interrupt 1 type control bit. Set/cleared by software to specify falling edge/low level triggered external interrupts.
TCON.1	IE0	Interrupt 0 Edge flag. Set by hardware when external interrupt edge detected. Cleared when interrupt processed.
TCON.0	IT0	Interrupt 0 Type control bit. Set/cleared by software to specify falling edge/low level triggered external interrupts.

SU00604C

Figure 3. Timer/Counter Control (TCON) Register

timer register is loaded with FFFF hex. The underflow also sets the TF2 flag, which can generate an interrupt if enabled.

The external flag EXF2 toggles when Timer 2 underflows or overflows. This EXF2 bit can be used as a 17th bit of resolution, if needed. the EXF2 flag does not generate an interrupt in this mode. As the baud rate generator, timer T2 is incremented by TCLK.

Baud Rate Generator Mode
By setting the TCLKn and/or RCLKn in T2CON or T2MOD, the Timer 2 can be chosen as the baud rate generator for either or both UARTs. The baud rates for transmit and receive can be simultaneously different.

Programmable Clock-Out

A 50% duty cycle clock can be programmed to come out on P1.6. This pin, besides being a regular I/O pin, has two alternate functions. It can be programmed (1) to input the external clock for Timer/Counter 2 or (2) to output a 50% duty cycle clock ranging from 3.58Hz to 3.75MHz at a 30MHz operating frequency.

To configure the Timer/Counter 2 as a clock generator, bit C/T2 (in T2CON) must be cleared and bit T20E in T2MOD must be set. Bit TR2 (T2CON.2) also must be set to start the timer.

The Clock-Out frequency depends on the oscillator frequency and the reload value of Timer 2 capture registers (TCAP2H, TCAP2L) as shown in this equation:

$$\frac{\text{TCLK}}{2 \times (65536 - \text{TCAP2H, TCAP2L})}$$

In the Clock-Out mode Timer 2 roll-overs will not generate an interrupt. This is similar to when it is used as a baud-rate generator. It is possible to use Timer 2 as a baud-rate generator and a clock generator simultaneously. Note, however, that the baud-rate will be 1/8 of the Clock-Out frequency.

Table 1. Timer 2 Operating Modes

TR2	CP/RL2	RCLK+TCLK	DCEN	MODE
0	X	X	X	Timer off (stopped)
1	0	0	0	16-bit auto-reload, counting up
1	0	0	1	16-bit auto-reload, counting up or down depending on T2EX pin
1	1	0	X	16-bit capture
1	X	1	X	Baud rate generator

TSTAT Address:411

WATCHDOG TIMER

The watchdog timer subsystem protects the system from incorrect code execution by causing a system reset when the watchdog timer underflows as a result of a failure of software to feed the timer prior to the timer reaching its terminal count. It is important to note that the watchdog timer is running after any type of reset and must be turned off by user software if the application does not use the watchdog function.

Watchdog Function

The watchdog consists of a programmable prescaler and the main timer. The prescaler derives its clock from the TCLK source that also drives timers 0, 1, and 2. The watchdog timer subsystem consists of a programmable 13-bit prescaler, and an 8-bit main timer. The main timer is clocked (decremented) by a tap taken from one of the top 8-bits of the prescaler as shown in Figure 10. The clock source for the prescaler is the same as TCLK (same as the clock source for the timers). Thus the main counter can be clocked as often as once every 32 TCLKs (see Table 2). The watchdog generates an underflow signal (and is autoloaded from WDL) when the watchdog is at count 0 and the clock to decrement the watchdog occurs. The watchdog is 8 bits wide and the autoload value can range from 0 to FFH. (The autoload value of 0 is permissible since the prescaler is cleared upon autoload).

This leads to the following user design equations. Definitions: t_{OSC} is the oscillator period, N is the selected prescaler tap value, W is the main counter autoload value, P is the prescaler value from Table 2, t_{MIN} is the minimum watchdog time-out value (when the autoload value is 0), t_{MAX} is the maximum time-out value (when the autoload value is FFH), t_D is the design time-out value.

$t_{MIN} = t_{OSC} \times 4 \times 32$ (W = 0, N = 4)

$t_{MAX} = t_{OSC} \times 64 \times 4096 \times 256$ (W = 255, N = 64)

$t_D = t_{OSC} \times N \times P \times (W + 1)$

The watchdog timer is not directly loadable by the user. Instead, the value to be loaded into the main timer is held in an autoload register. In order to cause the main timer to be loaded with the appropriate value, a special sequence of software action must take place. This operation is referred to as feeding the watchdog timer.

To feed the watchdog, two instructions must be sequentially executed successfully. No intervening SFR accesses are allowed, so interrupts should be disabled before feeding the watchdog. The instructions should move A5H to the WFEED1 register and then 5AH to the WFEED2 register. If WFEED1 is correctly loaded and WFEED2 is not correctly loaded, then an immediate watchdog reset will occur. The program sequence to feed the watchdog timer or cause new WDCON settings to take effect is as follows:

```
clr     ea              ; disable global interrupts.
mov.b   wfeed1,#A5h     ; do watchdog feed part 1
mov.b   wfeed2,#5Ah     ; do watchdog feed part 2
setb    ea              ; re-enable global interrupts.
```

This sequence assumes that the XA interrupt system is enabled and there is a possibility of an interrupt request occurring during the feed sequence. If an interrupt was allowed to be serviced and the service routine contained any SFR access, it would trigger a watchdog reset. If it is known that no interrupt could occur during the feed sequence, the instructions to disable and re-enable interrupts may be removed.

The software must be written so that a feed operation takes place every t_D seconds from the last feed operation. Some tradeoffs may need to be made. It is not advisable to include feed operations in minor loops or in subroutines unless the feed operation is a specific subroutine.

To turn the watchdog timer completely off, the following code sequence should be used:

```
mov.b   wdcon,#0        ; set WD control register to clear WDRUN.
mov.b   wfeed1,#A5h     ; do watchdog feed part 1
mov.b   wfeed2,#5Ah     ; do watchdog feed part 2
```

This sequence assumes that the watchdog timer is being turned off at the beginning of initialization code and that the XA interrupt system has not yet been enabled. If the watchdog timer is to be turned off at a point when interrupts may be enabled, instructions to disable and re-enable interrupts should be added to this sequence.

Watchdog Control Register (WDCON)

The reset values of the WDCON and WDL registers will be such that the watchdog timer has a timeout period of $4 \times 4096 \times t_{OSC}$ and the watchdog is running. WDCON can be written by software but the changes only take effect after executing a valid watchdog feed sequence.

Table 2. Prescaler Select Values in WDCON

PRE2	PRE1	PRE0	DIVISOR
0	0	0	32
0	0	1	64
0	1	0	128
0	1	1	256
1	0	0	512
1	0	1	1024
1	1	0	2048
1	1	1	4096

Watchdog Detailed Operation

When external $\overline{\text{RESET}}$ is applied, the following takes place:

- Watchdog run control bit set to ON (1).
- Autoload register WDL set to 00 (min. count).
- Watchdog time-out flag cleared.
- Prescaler is cleared.
- Prescaler tap set to the highest divide.
- Autoload takes place.

When coming out of a hardware reset, the software should load the autoload register and then feed the watchdog (cause an autoload).

If the watchdog is running and happens to underflow at the time the external RESET is applied, the watchdog time-out flag will be cleared.

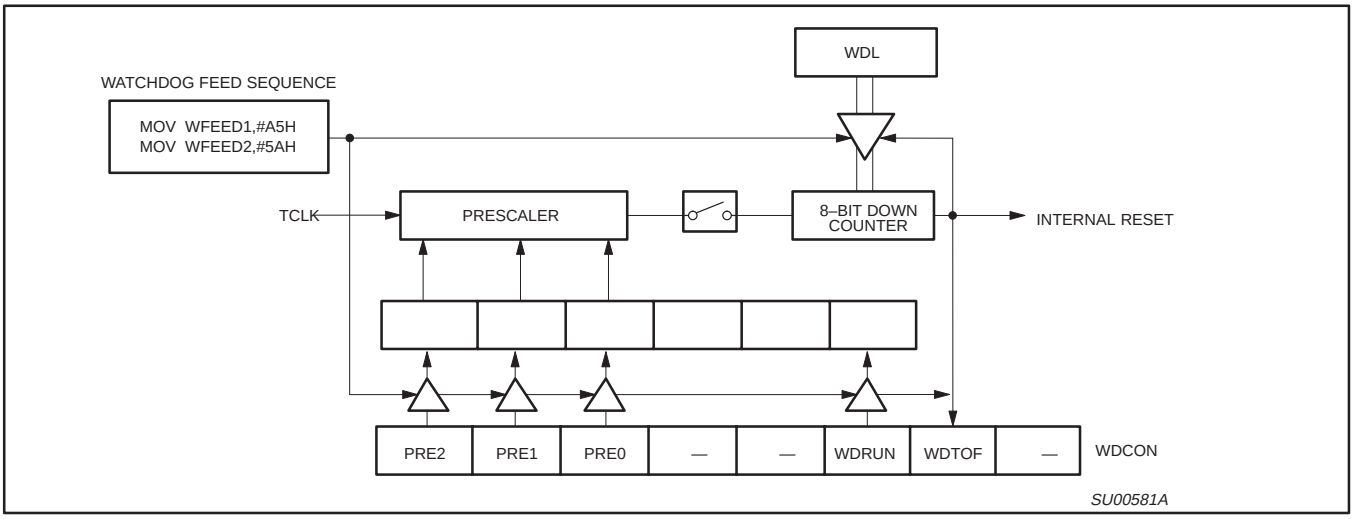

Figure 10. Watchdog Timer in XA-G30

When the watchdog underflows, the following action takes place (see Figure 10):

- Autoload takes place.
- Watchdog time-out flag is set
- Watchdog run bit unchanged.
- Autoload (WDL) register unchanged.
- Prescaler tap unchanged.
- All other device action same as external reset.

Note that if the watchdog underflows, the program counter will be loaded from the reset vector as in the case of an internal reset. The watchdog time-out flag can be examined to determine if the watchdog has caused the reset condition. The watchdog time-out flag bit can be cleared by software.

WDCON Register Bit Definitions

WDCON.7	PRE2	Prescaler Select 2, reset to 1
WDCON.6	PRE1	Prescaler Select 1, reset to 1
WDCON.5	PRE0	Prescaler Select 0, reset to 1
WDCON.4	—	
WDCON.3	—	
WDCON.2	WDRUN	Watchdog Run Control bit, reset to 1
WDCON.1	WDTOF	Timeout flag
WDCON.0	—	

UARTs

The XA-G30 includes 2 UART ports that are compatible with the enhanced UART used on the 8xC51FB. Baud rate selection is somewhat different due to the clocking scheme used for the XA timers.

Some other enhancements have been made to UART operation. The first is that there are separate interrupt vectors for each UART's transmit and receive functions. The UART transmitter has been double buffered, allowing packed transmission of data with no gaps between bytes and less critical interrupt service routine timing. A break detect function has been added to the UART. This operates independently of the UART itself and provides a start-of-break status bit that the program may test. Finally, an Overrun Error flag has been added to detect missed characters in the received data stream. The double buffered UART transmitter may require some software changes in code written for the original XA-G30 single buffered UART.

Each UART baud rate is determined by either a fixed division of the oscillator (in UART modes 0 and 2) or by the timer 1 or timer 2 overflow rate (in UART modes 1 and 3).

Timer 1 defaults to clock both UART0 and UART1. Timer 2 can be programmed to clock either UART0 through T2CON (via bits R0CLK and T0CLK) or UART1 through T2MOD (via bits R1CLK and T1CLK). In this case, the UART not clocked by T2 could use T1 as the clock source.

The serial port receive and transmit registers are both accessed at Special Function Register SnBUF. Writing to SnBUF loads the transmit register, and reading SnBUF accesses a physically separate receive register.

The serial port can operate in 4 modes:

Mode 0: Serial I/O expansion mode. Serial data enters and exits through RxDn. TxDn outputs the shift clock. 8 bits are transmitted/received (LSB first). (The baud rate is fixed at 1/16 the oscillator frequency.)

Mode 1: Standard 8-bit UART mode. 10 bits are transmitted (through TxDn) or received (through RxDn): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in Special Function Register SnCON. The baud rate is variable.

Mode 2: Fixed rate 9-bit UART mode. 11 bits are transmitted (through TxD) or received (through RxD): start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On Transmit, the 9th data bit (TB8_n in SnCON) can be assigned the value of 0 or 1. Or, for example, the parity bit (P, in the PSW) could be moved into TB8_n. On receive, the 9th data bit goes into RB8_n in Special Function Register SnCON, while the stop bit is ignored. The baud rate is programmable to 1/32 of the oscillator frequency.

Mode 3: Standard 9-bit UART mode. 11 bits are transmitted (through TxDn) or received (through RxDn): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). In fact, Mode 3 is the same as Mode 2 in all respects except baud rate. The baud rate in Mode 3 is variable.

In all four modes, transmission is initiated by any instruction that uses SnBUF as a destination register. Reception is initiated in Mode 0 by the condition RI_n = 0 and REN_n = 1. Reception is initiated in the other modes by the incoming start bit if REN_n = 1.

CLOCKING SCHEME/BAUD RATE GENERATION

The XA UARTS clock rates are determined by either a fixed division (modes 0 and 2) of the oscillator clock or by the Timer 1 or Timer 2 overflow rate (modes 1 and 3).

The clock for the UARTs in XA runs at 16x the Baud rate. If the timers are used as the source for Baud Clock, since maximum speed of timers/Baud Clock is Osc/4, the maximum baud rate is timer overflow divided by 16 i.e. Osc/64.

In Mode 0, it is fixed at Osc/16. In Mode 2, however, the fixed rate is Osc/32.

Pre-scaler for all Timers T0,1,2 controlled by PT1, PT0 bits in SCR	00	Osc/4
	01	Osc/16
	10	Osc/64
	11	reserved

Baud Rate for UART Mode 0:

Baud_Rate = Osc/16

Baud Rate calculation for UART Mode 1 and 3:

Baud_Rate = Timer_Rate/16

Timer_Rate = Osc/(N*(Timer_Range– Timer_Reload_Value))

where N = the TCLK prescaler value: 4, 16, or 64.
and Timer_Range = 256 for timer 1 in mode 2.
65536 for timer 1 in mode 0 and timer 2 in count up mode.

The timer reload value may be calculated as follows:

Timer_Reload_Value = Timer_Range–(Osc/(Baud_Rate*N*16))

NOTES:

1. The maximum baud rate for a UART in mode 1 or 3 is Osc/64.
2. The lowest possible baud rate (for a given oscillator frequency and N value) may be found by using a timer reload value of 0.
3. The timer reload value may never be larger than the timer range.
4. If a timer reload value calculation gives a negative or fractional result, the baud rate requested is not possible at the given oscillator frequency and N value.

Baud Rate for UART Mode 2:

Baud_Rate = Osc/32

Using Timer 2 to Generate Baud Rates

Timer T2 is a 16-bit up/down counter in XA. As a baud rate generator, timer 2 is selected as a clock source for either/both UART0 and UART1 transmitters and/or receivers by setting TCLKn and/or RCLKn in T2CON and T2MOD. As the baud rate generator, T2 is incremented as Osc/N where N = 4, 16 or 64 depending on TCLK as programmed in the SCR bits PT1, and PTO. So, if T2 is the source of one UART, the other UART could be clocked by either T1 overflow or fixed clock, and the UARTs could run independently with different baud rates.

SnSTAT Address: S0STAT 421
S1STAT 425

Bit Addressable
Reset Value: 00H

MSB							LSB
—	—	—	—	FEn	BRn	OEn	STINTn

BIT	SYMBOL	FUNCTION
SnSTAT.3	FEn	Framing Error flag is set when the receiver fails to see a valid STOP bit at the end of the frame. Cleared by software.
SnSTAT.2	BRn	Break Detect flag is set if a character is received with all bits (including STOP bit) being logic ‘0’. Thus it gives a “Start of Break Detect” on bit 8 for Mode 1 and bit 9 for Modes 2 and 3. The break detect feature operates independently of the UARTs and provides the START of Break Detect status bit that a user program may poll. Cleared by software.
SnSTAT.1	OEn	Overrun Error flag is set if a new character is received in the receiver buffer while it is still full (before the software has read the previous character from the buffer), i.e., when bit 8 of a new byte is received while RI in SnCON is still set. Cleared by software.
SnSTAT.0	STINTn	This flag must be set to enable any of the above status flags to generate a receive interrupt (RIn). The only way it can be cleared is by a software write to this register.

SU00607B

Figure 11. Serial Port Extended Status (SnSTAT) Register (See also Figure 13 regarding Framing Error flag)

UART INTERRUPT SCHEME

There are separate interrupt vectors for each UART's transmit and receive functions.

Table 3. Vector Locations for UARTs in XA

Vector Address	Interrupt Source	Arbitration
A0H – A3H	UART 0 Receiver	7
A4H – A7H	UART 0 Transmitter	8
A8H – ABH	UART 1 Receiver	9
ACH – AFH	UART 1 Transmitter	10

NOTE:
The transmit and receive vectors could contain the same ISR address to work like a 8051 interrupt scheme

Error Handling, Status Flags and Break Detect
The UARTs in XA has the following error flags; see Figure 11.

Multiprocessor Communications

Modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received. The 9th one goes into RB8. Then comes a stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1. This feature is enabled by setting bit SM2 in SCON. A way to use this feature in multiprocessor systems is as follows:

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte which identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be coming. The slaves that weren't being addressed leave their SM2s set and go on about their business, ignoring the coming data bytes.

SM2 has no effect in Mode 0, and in Mode 1 can be used to check the validity of the stop bit although this is better done with the Framing Error (FE) flag. In a Mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

Automatic Address Recognition
Automatic Address Recognition is a feature which allows the UART to recognize certain addresses in the serial bit stream by using hardware to make the comparisons. This feature saves a great deal of software overhead by eliminating the need for the software to examine every serial address which passes by the serial port. This feature is enabled by setting the SM2 bit in SCON. In the 9 bit UART modes, mode 2 and mode 3, the Receive Interrupt flag (RI) will be automatically set when the received byte contains either the "Given" address or the "Broadcast" address. The 9 bit mode requires that the 9th information bit is a 1 to indicate that the received information is an address and not data. Automatic address recognition is shown in Figure 14.

Using the Automatic Address Recognition feature allows a master to selectively communicate with one or more slaves by invoking the Given slave address or addresses. All of the slaves may be contacted by using the Broadcast address. Two special Function Registers are used to define the slave's address, SADDR, and the address mask, SADEN. SADEN is used to define which bits in the SADDR are to be used and which bits are "don't care". The SADEN mask can be logically ANDed with the SADDR to create the "Given" address which the master will use for addressing each of the slaves. Use of the Given address allows multiple slaves to be recognized while excluding others. The following examples will help to show the versatility of this scheme:

Slave 0	SADDR	=	1100 0000
	SADEN	=	1111 1101
	Given	=	1100 00X0
Slave 1	SADDR	=	1100 0000
	SADEN	=	1111 1110
	Given	=	1100 000X

In the above example SADDR is the same and the SADEN data is used to differentiate between the two slaves. Slave 0 requires a 0 in bit 0 and it ignores bit 1. Slave 1 requires a 0 in bit 1 and bit 0 is ignored. A unique address for Slave 0 would be 1100 0010 since slave 1 requires a 0 in bit 1. A unique address for slave 1 would be 1100 0001 since a 1 in bit 0 will exclude slave 0. Both slaves can be selected at the same time by an address which has bit 0 = 0 (for slave 0) and bit 1 = 0 (for slave 1). Thus, both could be addressed with 1100 0000.

In a more complex system the following could be used to select slaves 1 and 2 while excluding slave 0:

Slave 0	SADDR	=	1100 0000
	SADEN	=	1111 1001
	Given	=	1100 0XX0
Slave 1	SADDR	=	1110 0000
	SADEN	=	1111 1010
	Given	=	1110 0X0X
Slave 2	SADDR	=	1110 0000
	SADEN	=	1111 1100
	Given	=	1110 00XX

In the above example the differentiation among the 3 slaves is in the lower 3 address bits. Slave 0 requires that bit 0 = 0 and it can be uniquely addressed by 1110 0110. Slave 1 requires that bit 1 = 0 and it can be uniquely addressed by 1110 and 0101. Slave 2 requires that bit 2 = 0 and its unique address is 1110 0011. To select Slaves 0 and 1 and exclude Slave 2 use address 1110 0100, since it is necessary to make bit 2 = 1 to exclude slave 2.

The Broadcast Address for each slave is created by taking the logical OR of SADDR and SADEN. Zeros in this result are teated as don't-cares. In most cases, interpreting the don't-cares as ones, the broadcast address will be FF hexadecimal.

Upon reset SADDR and SADEN are loaded with 0s. This produces a given address of all "don't cares" as well as a Broadcast address of all "don't cares". This effectively disables the Automatic Addressing mode and allows the microcontroller to use standard UART drivers which do not make use of this feature.

SnCON Address: S0CON 420
S1CON 424

Bit Addressable
Reset Value: 00H

MSB							LSB
SM0	SM1	SM2	REN	TB8	RB8	TI	RI

Where SM0, SM1 specify the serial port mode, as follows:

SM0	SM1	Mode	Description	Baud Rate
0	0	0	shift register	$f_{OSC}/16$
0	1	1	8-bit UART	variable
1	0	2	9-bit UART	$f_{OSC}/32$
1	1	3	9-bit UART	variable

BIT	SYMBOL	FUNCTION
SnCON.5	SM2	Enables the multiprocessor communication feature in Modes 2 and 3. In Mode 2 or 3, if SM2 is set to 1, then RI will not be activated if the received 9th data bit (RB8) is 0. In Mode 1, if SM2=1 then RI will not be activated if a valid stop bit was not received. In Mode 0, SM2 should be 0.
SnCON.4	REN	Enables serial reception. Set by software to enable reception. Clear by software to disable reception.
SnCON.3	TB8	The 9th data bit that will be transmitted in Modes 2 and 3. Set or clear by software as desired. The TB8 bit is not double buffered. See text for details.
SnCON.2	RB8	In Modes 2 and 3, is the 9th data bit that was received. In Mode 1, if SM2=0, RB8 is the stop bit that was received. In Mode 0, RB8 is not used.
SnCON.1	TI	Transmit interrupt flag. Set when another byte may be written to the UART transmitter. See text for details. Must be cleared by software.
SnCON.0	RI	Receive interrupt flag. Set by hardware at the end of the 8th bit time in Mode 0, or at the end of the stop bit time in the other modes (except see SM2). Must be cleared by software.

I/O PORT OUTPUT CONFIGURATION

Each I/O port pin can be user configured to one of 4 output types. The types are Quasi-bidirectional (essentially the same as standard 80C51 family I/O ports), Open-Drain, Push-Pull, and Off (high impedance). The default configuration after reset is Quasi-bidirectional. However, in the ROMless mode (the $\overline{EA}$ pin is low at reset), the port pins that comprise the external data bus will default to push-pull outputs.

I/O port output configurations are determined by the settings in port configuration SFRs. There are 2 SFRs for each port, called PnCFGA and PnCFGB, where “n” is the port number. One bit in each of the 2 SFRs relates to the output setting for the corresponding port pin, allowing any combination of the 2 output types to be mixed on those port pins. For instance, the output type of port 1 pin 3 is controlled by the setting of bit 3 in the SFRs P1CFGA and P1CFGB.

Table 4 shows the configuration register settings for the 4 port output types. The electrical characteristics of each output type may be found in the DC Characteristic table.

Table 4. Port Configuration Register Settings

PnCFGB	PnCFGA	Port Output Mode
0	0	Open Drain
0	1	Quasi-bidirectional
1	0	Off (high impedance)
1	1	Push-Pull

NOTE:
Mode changes may cause glitches to occur during transitions. When modifying both registers, WRITE instructions should be carried out consecutively.

EXTERNAL BUS

The external program/data bus allows for 8-bit or 16-bit bus width, and address sizes from 12 to 20 bits. The bus width is selected by an input at reset (see Reset Options below), while the address size is set by the program in a configuration register. If all off-chip code is selected (through the use of the $\overline{EA}$ pin), the initial code fetches will be done with the maximum address size (20 bits).

RESET

The device is reset whenever a logic “0“ is applied to $\overline{RST}$ for at least 10 microseconds, placing a low level on the pin re-initializes the on-chip logic. Reset must be asserted when power is initially applied to the XA and held until the oscillator is running.

The duration of reset must be extended when power is initially applied or when using reset to exit power down mode. This is due to the need to allow the oscillator time to start up and stabilize. For most power supply ramp up conditions, this time is 10 milliseconds.

As it is brought high again, an exception is generated which causes the processor to jump to the address contained in the memory location 0000. The destination of the reset jump must be located in the first 64k of code address on power-up, all vectors are 16-bit values and so point to page zero addresses only. After a reset the RAM contents are indeterminate.

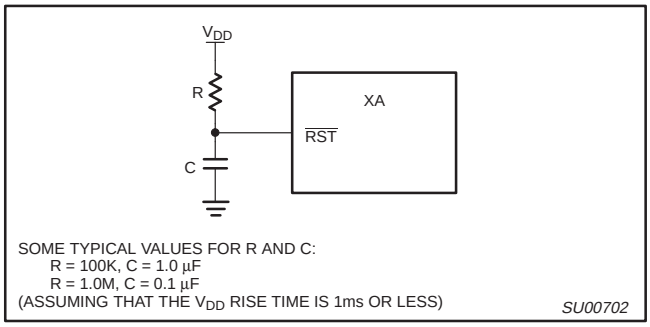

Figure 15. Recommended Reset Circuit

RESET OPTIONS

The $\overline{EA}$ pin is sampled on the rising edge of the $\overline{RST}$ pulse, and determines whether the device is to begin execution from internal or external code memory. $\overline{EA}$ pulled high configures the XA in single-chip mode. If $\overline{EA}$ is driven low, the device enters ROMless mode. After Reset is released, the $\overline{EA}$/WAIT pin becomes a bus wait signal for external bus transactions.

The BUSW/P3.5 pin is weakly pulled high while reset is asserted, allowing simple biasing of the pin with a resistor to ground to select the alternate bus width. If the BUSW pin is not driven at reset, the weak pullup will cause a 1 to be loaded for the bus width, giving a 16-bit external bus. BUSW may be pulled low with a 2.7K or smaller value resistor, giving an 8-bit external bus. The bus width setting from the BUSW pin may be overridden by software once the user program is running.

Both $\overline{EA}$ and BUSW must be held for three oscillator clock times after reset is deasserted to guarantee that their values are latched correctly.

POWER REDUCTION MODES

The XA-G30 supports Idle and Power Down modes of power reduction. The idle mode leaves some peripherals running to allow them to wake up the processor when an interrupt is generated. The power down mode stops the oscillator in order to minimize power. The processor can be made to exit power down mode via reset or one of the external interrupt inputs. In order to use an external interrupt to re-activate the XA while in power down mode, the external interrupt must be enabled and be configured to level sensitive mode. In power down mode, the power supply voltage may be reduced to the RAM keep-alive voltage (2 V), retaining the RAM, register, and SFR values at the point where the power down mode was entered.

ABSOLUTE MAXIMUM RATINGS

PARAMETER	RATING	UNIT
Operating temperature under bias	–55 to +125	°C
Storage temperature range	–65 to +150	°C
Voltage on $\overline{EA}/V_{PP}$ pin to V_{SS}	0 to +13.0	V
Voltage on any other pin to V_{SS}	–0.5 to V_{DD}+0.5 V	V
Maximum I_{OL} per I/O pin	15	mA
Power dissipation (based on package heat transfer limitations, not device power consumption)	1.5	W

DC ELECTRICAL CHARACTERISTICS

V_{DD} = 2.7 V to 5.5 V unless otherwise specified; V_{DD} = T_{amb} = 0 to 70 °C for commercial, –40 °C to +85 °C for industrial, unless otherwise specified.

SYMBOL	PARAMETER	TEST CONDITIONS	LIMITS			UNIT

I_{LI}	Input leakage current, P0–3[5]	V_{IN} = V_{IL} or V_{IH}	–		±10	µA
I_{TL}	Logical 1 to 0 transition current all ports[4]	At 5.5 V	–		–650	µA

NOTES:
1. Ports in Quasi bi-directional mode with weak pull-up (applies to ALE, $\overline{PSEN}$ only during RESET).
2. Ports in Push-Pull mode, both pull-up and pull-down assumed to be same strength
3. In all output modes
4. Port pins source a transition current when used in quasi-bidirectional mode and externally driven from 1 to 0. This current is highest when V_{IN} is approximately 2 V.
5. Measured with port in high impedance output mode.
6. Measured with port in quasi-bidirectional output mode.
7. Load capacitance for all outputs=80 pF.
8. Under steady state (non-transient) conditions, I_{OL} must be externally limited as follows:
   Maximum I_{OL} per port pin: 15 mA (*NOTE: This is 85°C specification for V_{DD} = 5 V.)
   Maximum I_{OL} per 8-bit port: 26 mA
   Maximum total I_{OL} for all output: 71 mA
   If I_{OL} exceeds the test condition, V_{OL} may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.
9. See Figures 25, 26, 29, and 30 for I_{DD} test conditions, and Figures 27 and 28 for I_{CC} vs. Frequency.
   Max. 5 V Active I_{DD} = (fosc × 1.33 mA) + 5 mA
   Max. 5 V Idle I_{ID} = (fosc × 0.87 mA) + 4 mA
10. V_{DDMIN} = 2.85 V operating at f_{OSC} = 30 MHz and –40 °C to +85 °C

Wait Input					
t_{WTH}	21	WAIT stable after bus strobe ($\overline{RD}$, $\overline{WR}$, or $\overline{PSEN}$) asserted		$(V10 * t_C) – 30$	ns
t_{WTL}	21	WAIT hold after bus strobe ($\overline{RD}$, $\overline{WR}$, or $\overline{PSEN}$) assertion	$(V10 * t_C) – 5$		ns

NOTES ON PAGE 23.

AC ELECTRICAL CHARACTERISTICS (V_{DD} = 2.7 V to 4.5 V)

T_{amb} = 0 to +70 °C for commercial, –40 °C to +85 °C for industrial.

SYMBOL	FIGURE	PARAMETER	VARIABLE CLOCK		UNIT
			MIN	MAX	
Address Cycle					
t_{CRAR}	21	Delay from clock rising edge to ALE rising edge	15	60	ns
t_{LHLL}	16	ALE pulse width (programmable)	(V1 * t_C) – 10		ns
t_{AVLL}	16	Address valid to ALE de-asserted (set-up)	(V1 * t_C) – 18		ns
t_{LLAX}	16	Address hold after ALE de-asserted	(t_C/2) – 12		ns
Code Read Cycle					
t_{PLPH}	16	$\overline{PSEN}$ pulse width	(V2 * t_C) – 12		ns
t_{LLPL}	16	ALE de-asserted to $\overline{PSEN}$ asserted	(t_C/2) – 9		ns
t_{AVIVA}	16	Address valid to instruction valid, ALE cycle (access time)		(V3 * t_C) – 58	ns
t_{AVIVB}	17	Address valid to instruction valid, non-ALE cycle (access time)		(V4 * t_C) – 52	ns
t_{PLIV}	16	$\overline{PSEN}$ asserted to instruction valid (enable time)		(V2 * t_C) – 52	ns
t_{PXIX}	16	Instruction hold after $\overline{PSEN}$ de-asserted	0		ns
t_{PXIZ}	16	Bus 3-State after $\overline{PSEN}$ de-asserted (disable time)		t_C – 8	ns
t_{IXUA}	16	Hold time of unlatched part of address after instruction latched	0		ns
Data Read Cycle					
t_{RLRH}	18	$\overline{RD}$ pulse width	(V7 * t_C) – 12		ns
t_{LLRL}	18	ALE de-asserted to $\overline{RD}$ asserted	(t_C/2) – 9		ns
t_{AVDVA}	18	Address valid to data input valid, ALE cycle (access time)		(V6 * t_C) – 58	ns
t_{AVDVB}	19	Address valid to data input valid, non-ALE cycle (access time)		(V5 * t_C) – 52	ns
t_{RLDV}	18	$\overline{RD}$ low to valid data in, enable time		(V7 * t_C) – 52	ns
t_{RHDX}	18	Data hold time after $\overline{RD}$ de-asserted	0		ns
t_{RHDZ}	18	Bus 3-State after $\overline{RD}$ de-asserted (disable time)		t_C – 8	ns
t_{DXUA}	18	Hold time of unlatched part of address after data latched	0		ns
Data Write Cycle					
t_{WLWH}	20	$\overline{WR}$ pulse width	(V8 * t_C) – 12		ns
t_{LLWL}	20	ALE falling edge to $\overline{WR}$ asserted	(V12 * t_C) – 10		ns
t_{QVWX}	20	Data valid before $\overline{WR}$ asserted (data setup time)	(V13 * t_C) – 28		ns
t_{WHQX}	20	Data hold time after $\overline{WR}$ de-asserted (Note 6)	(V11 * t_C) – 8		ns
t_{AVWL}	20	Address valid to $\overline{WR}$ asserted (address setup time) (Note 5)	(V9 * t_C) – 28		ns
t_{UAWH}	20	Hold time of unlatched part of address after $\overline{WR}$ is de-asserted	(V11 * t_C) – 10		ns
Wait Input					
t_{WTH}	21	WAIT stable after bus strobe ($\overline{RD}$, $\overline{WR}$, or $\overline{PSEN}$) asserted		(V10 * t_C) – 40	ns
t_{WTL}	21	WAIT hold after bus strobe ($\overline{RD}$, $\overline{WR}$, or $\overline{PSEN}$) assertion	(V10 * t_C) – 5		ns

NOTES:

1. Load capacitance for all outputs = 80 pF.
2. Variables V1 through V13 reflect programmable bus timing, which is programmed via the Bus Timing registers (BTRH and BTRL). Refer to the *XA User Guide* for details of the bus timing settings.
   - V1) This variable represents the programmed width of the ALE pulse as determined by the ALEW bit in the BTRL register. V1 = 0.5 if the ALEW bit = 0, and 1.5 if the ALEW bit = 1.
   - V2) This variable represents the programmed width of the $\overline{PSEN}$ pulse as determined by the CR1 and CR0 bits or the CRA1, CRA0, and ALEW bits in the BTRL register.
     - For a bus cycle with **no** ALE, V2 = 1 if CR1/0 = 00, 2 if CR1/0 = 01, 3 if CR1/0 = 10, and 4 if CR1/0 = 11. Note that during burst mode code fetches, $\overline{PSEN}$ does not exhibit transitions at the boundaries of bus cycles. V2 still applies for the purpose of determining peripheral timing requirements.
     - For a bus cycle **with** an ALE, V2 = the total bus cycle duration (2 if CRA1/0 = 00, 3 if CRA1/0 = 01, 4 if CRA1/0 = 10, and 5 if CRA1/0 = 11) minus the number of clocks used by ALE (V1 + 0.5).
       Example: If CRA1/0 = 10 and ALEW = 1, the V2 = 4 – (1.5 + 0.5) = 2.

Data sheet status

Data sheet status [1]	Product status [2]	Definitions
Objective data	Development	This data sheet contains data from the objective specification for product development. Philips Semiconductors reserves the right to change the specification in any manner without notice.
Preliminary data	Qualification	This data sheet contains data from the preliminary specification. Supplementary data will be published at a later date. Philips Semiconductors reserves the right to change the specification without notice, in order to improve the design and supply the best possible product.
Product data	Production	This data sheet contains data from the product specification. Philips Semiconductors reserves the right to make changes at any time in order to improve the design, manufacturing and supply. Changes will be communicated according to the Customer Product/Process Change Notification (CPCN) procedure SNW-SQ-650A.

[1] Please consult the most recently issued data sheet before initiating or completing a design.

[2] The product status of the device(s) described in this data sheet may have changed since this data sheet was published. The latest information is available on the Internet at URL http://www.semiconductors.philips.com.

Definitions

Short-form specification — The data in a short-form specification is extracted from a full data sheet with the same type number and title. For detailed information see the relevant data sheet or data handbook.

Limiting values definition — Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 60134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.

Application information — Applications that are described herein for any of these products are for illustrative purposes only. Philips Semiconductors make no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Disclaimers

Life support — These products are not designed for use in life support appliances, devices or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips Semiconductors customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips Semiconductors for any damages resulting from such application.

Right to make changes — Philips Semiconductors reserves the right to make changes, without notice, in the products, including circuits, standard cells, and/or software, described or contained herein in order to improve design and/or performance. Philips Semiconductors assumes no responsibility or liability for the use of any of these products, conveys no license or title under any patent, copyright, or mask work right to these products, and makes no representations or warranties that these products are free from patent, copyright, or mask work right infringement, unless otherwise specified.
