
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	PIC
Core Size	16-Bit
Speed	32MHz
Connectivity	I²C, IrDA, SPI, UART/USART, USB OTG
Peripherals	Brown-out Detect/Reset, LVD, POR, PWM, WDT
Number of I/O	52
Program Memory Size	256KB (85.5K x 24)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	96K x 8
Voltage - Supply (Vcc/Vdd)	2.2V ~ 3.6V
Data Converters	A/D 16x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	64-VFQFN Exposed Pad
Supplier Device Package	64-VQFN (9x9)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic24fj256gb206-i-mr

TABLE 1-3: PIC24FJ256GB210 FAMILY PINOUT DESCRIPTIONS (CONTINUED)

Function	Pin Number			I/O	Input Buffer	Description

VUSB	35	55	H9	P	—	USB Voltage (3.3V).

Legend: TTL = TTL input buffer; ST = Schmitt Trigger input buffer; ANA = Analog level input/output; I^2C™ = I^2C/SMBus input buffer

Note 1: The alternate EPMP pins are selected when the $\overline{\text{ALTPMP}}$ (CW3<12>) bit is programmed to '0'.

2: The PMSC2 signal will replace the PMA15 signal on the 15-pin PMA when CSF<1:0> = 01 or 10.

3: The PMCS1 signal will replace the PMA14 signal on the 14-pin PMA when CSF<1:0> = 10.

4: The alternate VREF pins selected when the $\overline{\text{ALTVREF}}$ (CW1<5>) bit is programmed to '0'.

4.0 MEMORY ORGANIZATION

As Harvard architecture devices, PIC24F microcontrollers feature separate program and data memory spaces and busses. This architecture also allows direct access of program memory from the data space during code execution.

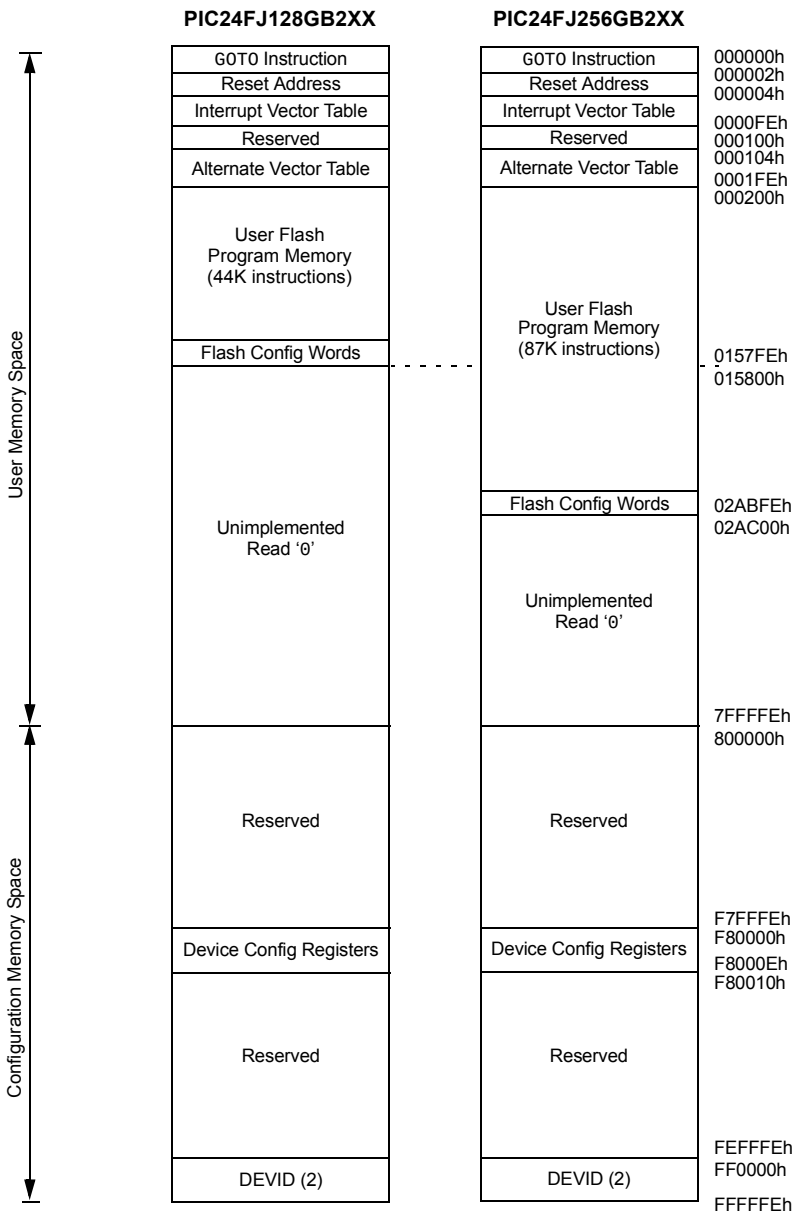
4.1 Program Memory Space

The program address memory space of the PIC24FJ256GB210 family devices is 4M instructions. The space is addressable by a 24-bit value derived from either the 23-bit Program Counter (PC) during program execution, or from table operation or data space remapping, as described in **Section 4.3 "Interfacing Program and Data Memory Spaces"**.

User access to the program memory space is restricted to the lower half of the address range (000000h to 7FFFFFh). The exception is the use of TBLRD/TBLWT operations, which use TBLPAG<7> to permit access to the Configuration bits and Device ID sections of the configuration memory space.

Memory maps for the PIC24FJ256GB210 family of devices are shown in Figure 4-1.

FIGURE 4-1: PROGRAM SPACE MEMORY MAP FOR PIC24FJ256GB210 FAMILY DEVICES



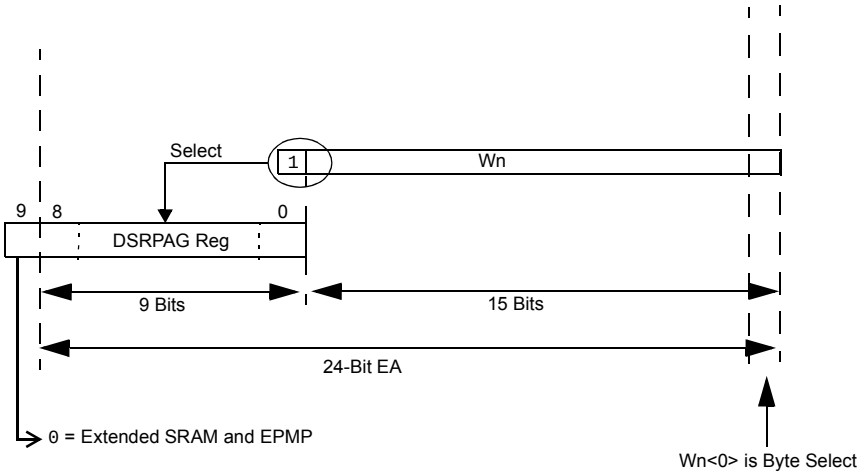
Note: Memory areas are not shown to scale.

4.2.5.1 Data Read from EDS Space

In order to read the data from the EDS space, first, an Address Pointer is set up by loading the required EDS page number into the DSRPAG register and assigning the offset address to one of the W registers. Once the above assignment is done, the EDS window is enabled by setting bit 15 of the working register, assigned with the offset address; then, the contents of the pointed EDS location can be read.

Figure 4-5 illustrates how the EDS space address is generated for read operations.

FIGURE 4-5: EDS ADDRESS GENERATION FOR READ OPERATIONS



When the Most Significant bit (MSb) of EA is '1' and DSRPAG<9> = 0, the lower 9 bits of DSRPAG are concatenated to the lower 15 bits of EA to form a 24-bit EDS space address for read operations.

Example 4-1 shows how to read a byte, word and double-word from EDS.

Note:	All read operations from EDS space have an overhead of one instruction cycle. Therefore, a minimum of two instruction cycles is required to complete an EDS read. EDS reads under the REPEAT instruction; the first two accesses take three cycles and the subsequent accesses take one cycle.

EXAMPLE 4-1: EDS READ CODE IN ASSEMBLY

```
; Set the EDS page from where the data to be read
    mov        #0x0002 , w0
    mov        w0 , DSRPAG    ;page 2 is selected for read
    mov        #0x0800 ,  w1  ;select the location (0x800) to be read
    bset       w1 , #15       ;set the MSB of the base address, enable EDS mode

;Read a byte from the selected location
    mov.b      [w1++] , w2    ;read Low byte
    mov.b      [w1++] , w3    ;read High byte

;Read a word from the selected location
    mov        [w1] , w2      ;

;Read Double - word from the selected location
    mov.d      [w1] , w2      ;two word read, stored in w2 and w3
```

7.0 INTERRUPT CONTROLLER

Note:	This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the "*PIC24F Family Reference Manual*", **Section 8. "Interrupts"** (DS39707). The information in this data sheet supersedes the information in the FRM.

The PIC24F interrupt controller reduces the numerous peripheral interrupt request signals to a single interrupt request signal to the PIC24F CPU. It has the following features:

- Up to 8 processor exceptions and software traps
- Seven user-selectable priority levels
- Interrupt Vector Table (IVT) with up to 118 vectors
- Unique vector for each interrupt or exception source
- Fixed priority within a specified user priority level
- Alternate Interrupt Vector Table (AIVT) for debug support
- Fixed interrupt entry and return latencies

7.1 Interrupt Vector Table

The Interrupt Vector Table (IVT) is shown in Figure 7-1. The IVT resides in program memory, starting at location 000004h. The IVT contains 126 vectors, consisting of 8 non-maskable trap vectors, plus up to 118 sources of interrupt. In general, each interrupt source has its own vector. Each interrupt vector contains a 24-bit wide address. The value programmed into each interrupt vector location is the starting address of the associated Interrupt Service Routine (ISR).

Interrupt vectors are prioritized in terms of their natural priority; this is linked to their position in the vector table. All other things being equal, lower addresses have a higher natural priority. For example, the interrupt associated with Vector 0 will take priority over interrupts at any other vector address.

PIC24FJ256GB210 family devices implement non-maskable traps and unique interrupts. These are summarized in Table 7-1 and Table 7-2.

7.1.1 ALTERNATE INTERRUPT VECTOR TABLE

The Alternate Interrupt Vector Table (AIVT) is located after the IVT, as shown in Figure 7-1. The ALTIVT (INTCON2<15>) control bit provides access to the AIVT. If the ALTIVT bit is set, all interrupt and exception processes will use the alternate vectors instead of the default vectors. The alternate vectors are organized in the same manner as the default vectors.

The AIVT supports emulation and debugging efforts by providing a means to switch between an application and a support environment without requiring the interrupt vectors to be reprogrammed. This feature also enables switching between applications for evaluation of different software algorithms at run time. If the AIVT is not needed, the AIVT should be programmed with the same addresses used in the IVT.

7.2 Reset Sequence

A device Reset is not a true exception because the interrupt controller is not involved in the Reset process. The PIC24F devices clear their registers in response to a Reset, which forces the PC to zero. The microcontroller then begins program execution at location, 000000h. The user programs a GOTO instruction at the Reset address, which redirects program execution to the appropriate start-up routine.

Note:	Any unimplemented or unused vector locations in the IVT and AIVT should be programmed with the address of a default interrupt handler routine that contains a RESET instruction.

8.3 Control Registers

The following four Special Function Registers control the operation of the oscillator:

- OSCCON
- CLKDIV
- OSCTUN
- REFOCON

The OSCCON register (Register 8-1) is the main control register for the oscillator. It controls clock source switching and allows the monitoring of clock sources.

The CLKDIV register (Register 8-2) controls the features associated with Doze mode, as well as the postscaler for the FRC oscillator.

The OSCTUN register (Register 8-3) allows the user to fine tune the FRC oscillator over a range of approximately ±1.5%.

The REFOCON register (Register 8-5) controls the frequency of the reference clock out.

REGISTER 8-1: OSCCON: OSCILLATOR CONTROL REGISTER

U-0	R-x, HSC(1)	R-x, HSC(1)	R-x, HSC(1)	U-0	R/W-x(1)	R/W-x(1)	R/W-x(1)
—	COSC2	COSC1	COSC0	—	NOSC2	NOSC1	NOSC0
bit 15							bit 8

R/S-0	R/W-0	R-0, HSC(3)	U-0	R/C-0, HS	R/W-0	R/W-0	R/W-0
CLKLOCK	IOLOCK(2)	LOCK	—	CF	POSCEN	SOSCEN	OSWEN
bit 7							bit 0

Legend:	C = Clearable bit	S = Settable bit	HSC = Hardware Settable/Clearable bit
R = Readable bit	W = Writable bit	U = Unimplemented bit, read as '0'	
-n = Value at POR	'1' = Bit is set	'0' = Bit is cleared	x = Bit is unknown
HS = Hardware Settable bit			

bit 15 **Unimplemented:** Read as '0'

bit 14-12 **COSC<2:0>:** Current Oscillator Selection bits(1)
- 111 = Fast RC Oscillator with Postscaler (FRCDIV)
- 110 = Fast RC/16 Oscillator
- 101 = Low-Power RC Oscillator (LPRC)
- 100 = Secondary Oscillator (SOSC)
- 011 = Primary Oscillator with PLL module (XTPLL, HSPLL, ECPLL)
- 010 = Primary Oscillator (XT, HS, EC)
- 001 = Fast RC Oscillator with Postscaler and PLL module (FRCPLL)
- 000 = Fast RC Oscillator (FRC)

bit 11 **Unimplemented:** Read as '0'

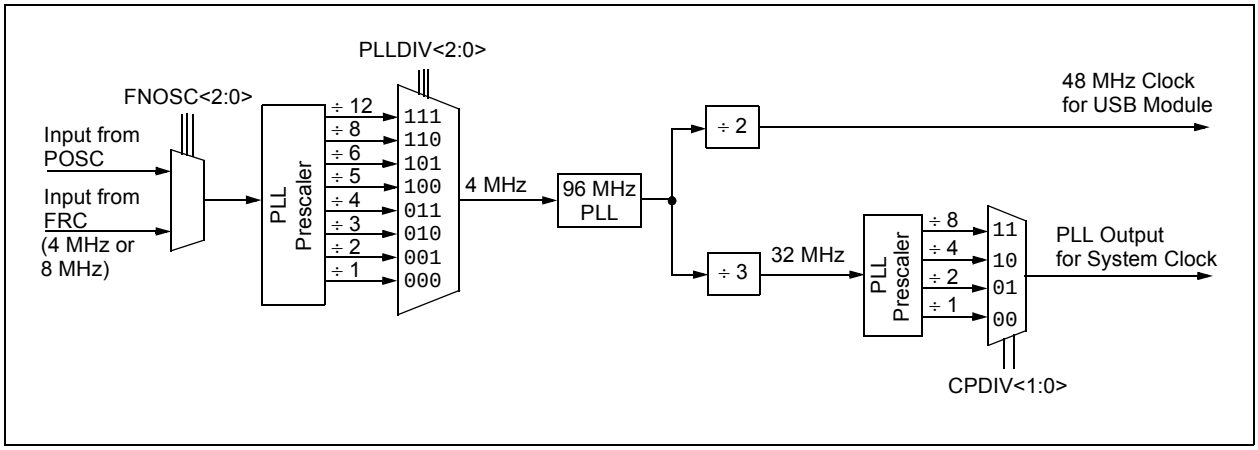
bit 10-8 **NOSC<2:0>:** New Oscillator Selection bits(1)
- 111 = Fast RC Oscillator with Postscaler (FRCDIV)
- 110 = Fast RC/16 Oscillator
- 101 = Low-Power RC Oscillator (LPRC)
- 100 = Secondary Oscillator (SOSC)
- 011 = Primary Oscillator with PLL module (XTPLL, HSPLL, ECPLL)
- 010 = Primary Oscillator (XT, HS, EC)
- 001 = Fast RC Oscillator with Postscaler and PLL module (FRCPLL)
- 000 = Fast RC Oscillator (FRC)

Note 1: Reset values for these bits are determined by the FNOSC Configuration bits.

2: The state of the IOLOCK bit can only be changed once an unlocking sequence has been executed. In addition, if the IOL1WAY Configuration bit is '1', once the IOLOCK bit is set, it cannot be cleared.

3: Also resets to '0' during any valid clock switch or whenever a non PLL Clock mode is selected.

FIGURE 8-2: 96 MHz PLL BLOCK



8.5.1 SYSTEM CLOCK GENERATION

The system clock is generated from the 96 MHz branch using a configurable postscaler/divider to generate a range of frequencies for the system clock multiplexer. The output of the multiplexer is further passed through a fixed divide-by-3 divider and the final output is used as the system clock. Figure 8-2 shows this logic in the system clock sub-block. Since the source is a 96 MHz signal, the possible system clock frequencies are listed in Table 8-2. The available system clock options are always the same, regardless of the setting of the PLLDIV Configuration bits.

TABLE 8-2: SYSTEM CLOCK OPTIONS FOR 96 MHz PLL BLOCK

MCU Clock Division (CPDIV<1:0>)	System Clock Frequency (Instruction Rate in MIPS)
None (00)	32 MHz (16)
÷2 (01)	16 MHz (8)
÷4 (10)	8 MHz (4)(1)
÷8 (11)	4 MHz (2)(1)

Note 1: These options are not compatible with USB operation. They may be used whenever the PLL branch is selected and the USB module is disabled.

bit 9 **ENFLT2:** Fault Input 2 Enable bit(2)
- 1 = Fault 2 (Comparator 1/2/3 out) is enabled(3)
- 0 = Fault 2 is disabled

bit 8 **ENFLT1:** Fault Input 1 Enable bit(2)
- 1 = Fault 1 (OCFB pin) is enabled(4)
- 0 = Fault 1 is disabled

bit 7 **ENFLT0:** Fault Input 0 Enable bit(2)
- 1 = Fault 0 (OCFA pin) is enabled(4)
- 0 = Fault 0 is disabled

bit 6 **OCFLT2:** PWM Fault 2 (Comparator 1/2/3) Condition Status bit(2,3)
- 1 = PWM Fault 2 has occurred
- 0 = No PWM Fault 2 has occurred

bit 5 **OCFLT1:** PWM Fault 1 (OCFB pin) Condition Status bit(2,4)
- 1 = PWM Fault 1 has occurred
- 0 = No PWM Fault 1 has occurred

bit 4 **OCFLT0:** PWM Fault 0 (OCFA pin) Condition Status bit(2,4)
- 1 = PWM Fault 0 has occurred
- 0 = No PWM Fault 0 has occurred

Note 1: The OCx output must also be configured to an available RPn pin. For more information, see **Section 10.4 "Peripheral Pin Select (PPS)"**.

2: The Fault input enable and Fault status bits are valid when OCM<2:0> = 111 or 110.

3: The Comparator 1 output controls the OC1-OC3 channels; Comparator 2 output controls the OC4-OC6 channels. Comparator 3 output controls the OC7-OC9 channels.

4: The OCFA/OCFB Fault input must also be configured to an available RPn/RPIn pin. For more information, see **Section 10.4 "Peripheral Pin Select (PPS)"**.

REGISTER 14-2: OCxCON2: OUTPUT COMPARE x CONTROL REGISTER 2 (CONTINUED)

00011 = Output Compare 3(1)
00010 = Output Compare 2(1)
00001 = Output Compare 1(1)
00000 = Not synchronized to any other module

Note 1: Never use an OC module as its own trigger source, either by selecting this mode or another equivalent SYNCSEL setting.
2: Use these inputs as trigger sources only and never as sync sources.
3: The DCB<1:0> bits are double-buffered in the PWM modes only (OCM<2:0> (OCxCON1<2:0>) = 111, 110).

BDs have a fixed relationship to a particular endpoint, depending on the buffering configuration. Table 18-2 provides the mapping of BDs to endpoints. This relationship also means that gaps may occur in the BDT if endpoints are not enabled contiguously. This, theoretically, means that the BDs for disabled endpoints could be used as buffer space. In practice, users should avoid using such spaces in the BDT unless a method of validating BD addresses is implemented.

18.2.1 BUFFER OWNERSHIP

Because the buffers and their BDs are shared between the CPU and the USB module, a simple semaphore mechanism is used to distinguish which is allowed to update the BD and associated buffers in memory. This is done by using the UOWN bit as a semaphore to distinguish which is allowed to update the BD and associated buffers in memory. UOWN is the only bit that is shared between the two configurations of BDnSTAT.

When UOWN is clear, the BD entry is “owned” by the microcontroller core. When the UOWN bit is set, the BD entry and the buffer memory are “owned” by the USB peripheral. The core should not modify the BD or its corresponding data buffer during this time. Note that the microcontroller core can still read BDnSTAT while the SIE owns the buffer and vice versa.

The Buffer Descriptors have a different meaning based on the source of the register update. Register 18-1 and Register 18-2 show the differences in BDnSTAT depending on its current “ownership”.

When UOWN is set, the user can no longer depend on the values that were written to the BDs. From this point, the USB module updates the BDs as necessary, overwriting the original BD values. The BDnSTAT register is updated by the SIE with the token PID and the transfer count is updated.

18.2.2 DMA INTERFACE

The USB OTG module uses a dedicated DMA to access both the BDT and the endpoint data buffers. Since part of the address space of the DMA is dedicated to the Buffer Descriptors, a portion of the memory connected to the DMA must comprise a contiguous address space properly mapped for the access by the module.

TABLE 18-2: ASSIGNMENT OF BUFFER DESCRIPTORS FOR THE DIFFERENT BUFFERING MODES

Endpoint	BDs Assigned to Endpoint							
	Mode 0 (No Ping-Pong)		Mode 1 (Ping-Pong on EP0 OUT)		Mode 2 (Ping-Pong on all EPs)		Mode 3 (Ping-Pong on all other EPs, except EP0)	
	Out	In	Out	In	Out	In	Out	In
0	0	1	0 (E), 1 (O)	2	0 (E), 1 (O)	2 (E), 3 (O)	0	1

NOTES:

28.0 INSTRUCTION SET SUMMARY

Note:	This chapter is a brief summary of the PIC24F instruction set architecture and is not intended to be a comprehensive reference source.

The PIC24F instruction set adds many enhancements to the previous PIC® MCU instruction sets, while maintaining an easy migration from previous PIC MCU instruction sets. Most instructions are a single program memory word. Only three instructions require two program memory locations.

Each single-word instruction is a 24-bit word divided into an 8-bit opcode, which specifies the instruction type and one or more operands, which further specify the operation of the instruction. The instruction set is highly orthogonal and is grouped into four basic categories:

- Word or byte-oriented operations
- Bit-oriented operations
- Literal operations
- Control operations

Table 28-1 shows the general symbols used in describing the instructions. The PIC24F instruction set summary in Table 28-2 lists all the instructions, along with the status flags affected by each instruction.

Most word or byte-oriented W register instructions (including barrel shift instructions) have three operands:

- The first source operand which is typically a register ‘Wb’ without any address modifier
- The second source operand which is typically a register ‘Ws’ with or without an address modifier
- The destination of the result which is typically a register ‘Wd’ with or without an address modifier

However, word or byte-oriented file register instructions have two operands:

- The file register specified by the value, ‘f’
- The destination, which could either be the file register, ‘f’, or the W0 register, which is denoted as ‘WREG’

Most bit-oriented instructions (including simple rotate/shift instructions) have two operands:

- The W register (with or without an address modifier) or file register (specified by the value of ‘Ws’ or ‘f’)
- The bit in the W register or file register (specified by a literal value or indirectly by the contents of register, ‘Wb’)

The literal instructions that involve data movement may use some of the following operands:

- A literal value to be loaded into a W register or file register (specified by the value of ‘k’)
- The W register or file register where the literal value is to be loaded (specified by ‘Wb’ or ‘f’)

However, literal instructions that involve arithmetic or logical operations use some of the following operands:

- The first source operand which is a register ‘Wb’ without any address modifier
- The second source operand which is a literal value
- The destination of the result (only if not the same as the first source operand), which is typically a register ‘Wd’ with or without an address modifier

The control instructions may use some of the following operands:

- A program memory address
- The mode of the table read and table write instructions

All instructions are a single word, except for certain double-word instructions, which were made double-word instructions so that all the required information is available in these 48 bits. In the second word, the 8 MSbs are ‘0’s. If this second word is executed as an instruction (by itself), it will execute as a NOP.

Most single-word instructions are executed in a single instruction cycle, unless a conditional test is true or the program counter is changed as a result of the instruction. In these cases, the execution takes two instruction cycles, with the additional instruction cycle(s) executed as a NOP. Notable exceptions are the BRA (unconditional/computed branch), indirect CALL/GOTO, all table reads and writes, and RETURN/RETFIE instructions, which are single-word instructions but take two or three cycles.

Certain instructions that involve skipping over the subsequent instruction require either two or three cycles if the skip is performed, depending on whether the instruction being skipped is a single-word or two-word instruction. Moreover, double-word moves require two cycles. The double-word instructions execute in two instruction cycles.
