
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	PIC
Core Size	8-Bit
Speed	48MHz
Connectivity	I²C, SPI, UART/USART, USB
Peripherals	Brown-out Detect/Reset, LVD, POR, PWM, WDT
Number of I/O	49
Program Memory Size	32KB (16K x 16)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	3.8K x 8
Voltage - Supply (Vcc/Vdd)	2V ~ 3.6V
Data Converters	A/D 8x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	64-TQFP
Supplier Device Package	64-TQFP (10x10)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic18f65j50-i-pt

TABLE 1-4: PIC18F8XJ5X PINOUT I/O DESCRIPTIONS (CONTINUED)

Pin Name	Pin Number	Pin Type	Buffer Type	Description
	80-TQFP			
				PORTC is a bidirectional I/O port.
RC0/T1OSO/T13CKI	36			
RC0		I/O	ST	Digital I/O.
T1OSO		O	—	Timer1 oscillator output.
T13CKI		I	ST	Timer1/Timer3 external clock input.
RC1/T1OSI/ECCP2/P2A	35			
RC1		I/O	ST	Digital I/O.
T1OSI		I	CMOS	Timer1 oscillator input.
ECCP2(2)		I/O	ST	Capture 2 input/Compare 2 output/PWM2 output.
P2A(2)		O	—	ECCP2 PWM output A.
RC2/ECCP1/P1A	43			
RC2		I/O	ST	Digital I/O.
ECCP1		I/O	ST	Capture 1 input/Compare 1 output/PWM1 output.
P1A		O	—	ECCP1 PWM output A.
RC3/SCK1/SCL1	44			
RC3		I/O	ST	Digital I/O.
SCK1		I/O	ST	Synchronous serial clock input/output for SPI mode.
SCL1		I/O	ST	Synchronous serial clock input/output for I^2C™ mode.
RC4/SDI1/SDA1	45			
RC4		I/O	ST	Digital I/O.
SDI1		I	ST	SPI data in.
SDA1		I/O	ST	I^2C data I/O.
RC5/SDO1/C2OUT	46			
RC5		I/O	ST	Digital I/O.
SDO1		O	—	SPI data out.
C2OUT		O	TTL	Comparator 2 output.
RC6/TX1/CK1	37			
RC6		I/O	ST	Digital I/O.
TX1		O	—	EUSART1 asynchronous transmit.
CK1		I/O	ST	EUSART1 synchronous clock (see related RX1/DT1).
RC7/RX1/DT1	38			
RC7		I/O	ST	Digital I/O.
RX1		I	ST	EUSART1 asynchronous receive.
DT1		I/O	ST	EUSART1 synchronous data (see related TX1/CK1).

Legend: TTL = TTL compatible input; CMOS = CMOS compatible input or output; ST = Schmitt Trigger input with CMOS levels; Analog = Analog input; I = Input; O = Output; P = Power; OD = Open-Drain (no P diode to V_{DD})

Note 1: Alternate assignment for ECCP2/P2A when CCP2MX Configuration bit is cleared (Extended Microcontroller mode).

2: Default assignment for ECCP2/P2A for all devices in all operating modes (CCP2MX is set).

3: Default assignments for P1B/P1C/P3B/P3C (ECCPMX Configuration bit is set).

4: Alternate assignment for ECCP2/P2A when CCP2MX is cleared (Microcontroller mode).

5: Alternate assignments for P1B/P1C/P3B/P3C (ECCPMX Configuration bit is cleared).

6: Pin placement when PMPMX = 1.

7: Pin placement when PMPMX = 0.

8: RA7 and RA6 will be disabled if OSC1 and OSC2 are used for the clock function.

2.5 Reference Clock Output

In addition to the peripheral clock/4 output in certain oscillator modes, the device clock in the PIC18F87J10 family can also be configured to provide a reference clock output signal to a port pin. This feature is available in all oscillator configurations and allows the user to select a greater range of clock submultiples to drive external devices in the application.

This reference clock output is controlled by the REFOCON register (Register 2-3). Setting the ROON bit (REFOCON<7>) makes the clock signal available on the REFO (RE3) pin. The RODIV3:RODIV0 bits enable the selection of 16 different clock divider options.

The ROSSLP and ROSEL bits (REFOCON<5:4>) control the availability of the reference output during Sleep mode. The ROSEL bit determines if the oscillator on OSC1 and OSC2, or the current system clock source, is used for the reference clock output. The ROSSLP bit determines if the reference source is available on RE3 when the device is in Sleep mode.

To use the reference clock output in Sleep mode, both the ROSSLP and ROSEL bits must be set. The device clock must also be configured for an EC or HS mode; otherwise, the oscillator on OSC1 and OSC2 will be powered down when the device enters Sleep mode. Clearing the ROSEL bit allows the reference output frequency to change as the system clock changes during any clock switches.

The REFOCON register is an alternate SFR and shares the same memory address as the OSCCON register. It is accessed by setting the ADSHR bit (WDTCON<4>) in the WDTCON register (see Register 25-9).

REGISTER 2-3: REFOCON: REFERENCE OSCILLATOR CONTROL REGISTER

R/W-0	U-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0
ROON	—	ROSSLP	ROSEL	RODIV3	RODIV2	RODIV1	RODIV0
bit 7							bit 0

Legend:			
R = Readable bit	W = Writable bit	U = Unimplemented bit, read as ‘0’	
-n = Value at POR	‘1’ = Bit is set	‘0’ = Bit is cleared	x = Bit is unknown

bit 7 **ROON:** Reference Oscillator Output Enable bit
1 = Reference oscillator enabled on REFO pin
0 = Reference oscillator disabled

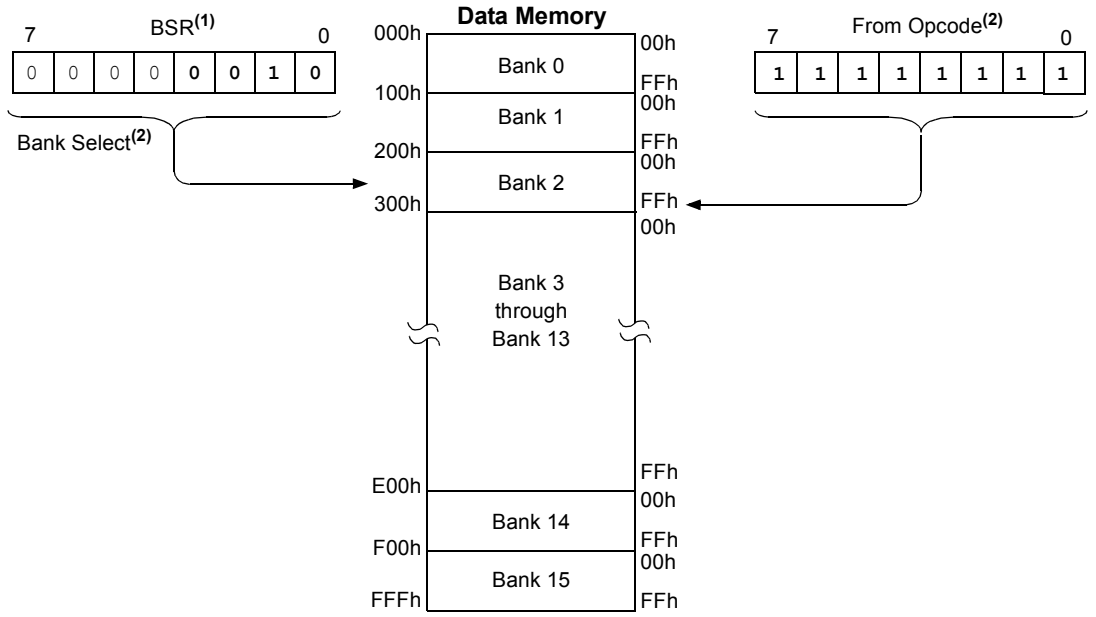
bit 6 **Unimplemented:** Read as ‘0’

bit 5 **ROSSLP:** Reference Oscillator Output Stop in Sleep bit
1 = Reference oscillator continues to run in Sleep
0 = Reference oscillator is disabled in Sleep

bit 4 **ROSEL:** Reference Oscillator Source Select bit
1 = Primary oscillator used as the base clock. Note that the crystal oscillator must be enabled using the FOSC2:FOSC0 bits; crystal maintains the operation in Sleep mode.
0 = System clock used as the base clock; base clock reflects any clock switching of the device

bit 3-0 **RODIV3:RODIV0:** Reference Oscillator Divisor Select bits
1111 = Base clock value divided by 32,768
1110 = Base clock value divided by 16,384
1101 = Base clock value divided by 8,192
1100 = Base clock value divided by 4,096
1011 = Base clock value divided by 2,048
1010 = Base clock value divided by 1,024
1001 = Base clock value divided by 512
1000 = Base clock value divided by 256
0111 = Base clock value divided by 128
0110 = Base clock value divided by 64
0101 = Base clock value divided by 32
0100 = Base clock value divided by 16
0011 = Base clock value divided by 8
0010 = Base clock value divided by 4
0001 = Base clock value divided by 2
0000 = Base clock value

FIGURE 5-8: USE OF THE BANK SELECT REGISTER (DIRECT ADDRESSING)



Note 1: The Access RAM bit of the instruction can be used to force an override of the selected bank (BSR<3:0>) to the registers of the Access Bank.

2: The `MOVFF` instruction embeds the entire 12-bit address in the instruction.

5.3.3 ACCESS BANK

While the use of the BSR with an embedded 8-bit address allows users to address the entire range of data memory, it also means that the user must always ensure that the correct bank is selected. Otherwise, data may be read from or written to the wrong location. This can be disastrous if a GPR is the intended target of an operation, but an SFR is written to instead. Verifying and/or changing the BSR for each read or write to data memory can become very inefficient.

To streamline access for the most commonly used data memory locations, the data memory is configured with an Access Bank, which allows users to access a mapped block of memory without specifying a BSR. The Access Bank consists of the first 96 bytes of memory (00h-5Fh) in Bank 0 and the last 160 bytes of memory (60h-FFh) in Bank 15. The lower half is known as the “Access RAM” and is composed of GPRs. The upper half is where the device’s SFRs are mapped. These two areas are mapped contiguously in the Access Bank and can be addressed in a linear fashion by an 8-bit address (Figure 5-7).

The Access Bank is used by core PIC18 instructions that include the Access RAM bit (the ‘a’ parameter in the instruction). When ‘a’ is equal to ‘`1`’, the instruction uses the BSR and the 8-bit address included in the opcode for the data memory address. When ‘a’ is ‘`0`’, however, the instruction is forced to use the Access Bank address map; the current value of the BSR is ignored entirely.

Using this “forced” addressing allows the instruction to operate on a data address in a single cycle without updating the BSR first. For 8-bit addresses of 60h and above, this means that users can evaluate and operate on SFRs more efficiently. The Access RAM below 60h is a good place for data values that the user might need to access rapidly, such as immediate computational results or common program variables. Access RAM also allows for faster and more code efficient context saving and switching of variables.

The mapping of the Access Bank is slightly different when the extended instruction set is enabled (XINST Configuration bit = `1`). This is discussed in more detail in **Section 5.6.3 “Mapping the Access Bank in Indexed Literal Offset Mode”**.

5.3.4 GENERAL PURPOSE REGISTER FILE

PIC18 devices may have banked memory in the GPR area. This is data RAM which is available for use by all instructions. GPRs start at the bottom of Bank 0 (address 000h) and grow upwards towards the bottom of the SFR area. GPRs are not initialized by a Power-on Reset and are unchanged on all other Resets.

7.0 EXTERNAL MEMORY BUS

Note: The External Memory Bus is not implemented on 64-pin devices.

The External Memory Bus (EMB) allows the device to access external memory devices (such as Flash, EPROM, SRAM, etc.) as program or data memory. It supports both 8 and 16-Bit Data Width modes and three address widths of up to 20 bits.

The bus is implemented with 28 pins, multiplexed across four I/O ports. Three ports (PORTD, PORTE and PORTH) are multiplexed with the address/data bus for a total of 20 available lines, while PORTJ is multiplexed with the bus control signals.

A list of the pins and their functions is provided in Table 7-1.

TABLE 7-1: PIC18F87J50 FAMILY EXTERNAL BUS – I/O PORT FUNCTIONS

Name	Port	Bit	External Memory Bus Function
RD0/AD0	PORTD	0	Address bit 0 or Data bit 0
RD1/AD1	PORTD	1	Address bit 1 or Data bit 1
RD2/AD2	PORTD	2	Address bit 2 or Data bit 2
RD3/AD3	PORTD	3	Address bit 3 or Data bit 3
RD4/AD4	PORTD	4	Address bit 4 or Data bit 4
RD5/AD5	PORTD	5	Address bit 5 or Data bit 5
RD6/AD6	PORTD	6	Address bit 6 or Data bit 6
RD7/AD7	PORTD	7	Address bit 7 or Data bit 7
RE0/AD8	PORTE	0	Address bit 8 or Data bit 8
RE1/AD9	PORTE	1	Address bit 9 or Data bit 9
RE2/AD10	PORTE	2	Address bit 10 or Data bit 10
RE3/AD11	PORTE	3	Address bit 11 or Data bit 11
RE4/AD12	PORTE	4	Address bit 12 or Data bit 12
RE5/AD13	PORTE	5	Address bit 13 or Data bit 13
RE6/AD14	PORTE	6	Address bit 14 or Data bit 14
RE7/AD15	PORTE	7	Address bit 15 or Data bit 15
RH0/A16	PORTH	0	Address bit 16
RH1/A17	PORTH	1	Address bit 17
RH2/A18	PORTH	2	Address bit 18
RH3/A19	PORTH	3	Address bit 19
RJ0/ALE	PORTJ	0	Address Latch Enable (ALE) Control pin
RJ1/$\overline{OE}$	PORTJ	1	Output Enable ($\overline{OE}$) Control pin
RJ2/$\overline{WRL}$	PORTJ	2	Write Low ($\overline{WRL}$) Control pin
RJ3/$\overline{WRH}$	PORTJ	3	Write High ($\overline{WRH}$) Control pin
RJ4/BA0	PORTJ	4	Byte Address bit 0 (BA0)
RJ5/$\overline{CE}$	PORTJ	5	Chip Enable ($\overline{CE}$) Control pin
RJ6/$\overline{LB}$	PORTJ	6	Lower Byte Enable ($\overline{LB}$) Control pin
RJ7/$\overline{UB}$	PORTJ	7	Upper Byte Enable ($\overline{UB}$) Control pin

Note: For the sake of clarity, only I/O port and external bus assignments are shown here. One or more additional multiplexed features may be available on some pins.

11.1.4 PMP MULTIPLEXING OPTIONS(80-PINS DEVICES)

By default, the PMP and the External Memory Bus (EMB) multiplex some of their signals to the same I/O pins on PORTD and PORTE. It is possible that some applications may require the use of both modules at the same time. For these instances, the 80-pin devices can be configured to multiplex the PMP to different I/O ports. PMP configuration is determined by the PMPMX Configuration bit setting; by default, the PMP and EMB modules share PORTD and PORTE. The optional pin configuration is shown in Table 11-1.

TABLE 11-1: PMP PIN MULTIPLEXING 80-PIN DEVICES

PMP Function	Pin Assignment	
	PMPMX = 1	**PMPMX=** 0
PMD0	PORTD<0>	PORTF<7>
PMD1	PORTD<1>	PORTF<6>
PMD2	PORTD<2>	PORTF<5>
PMD3	PORTD<3>	PORTH<4>
PMD4	PORTD<4>	PORTA<5>
PMD5	PORTD<5>	PORTA<4>
PMD6	PORTD<6>	PORTH<3>
PMD7	PORTD<7>	PORTH<2>
PMBE	PORTE<2>	PORTH<5>
PMWR	PORTE<1>	PORTH<7>
PMRD	PORTE<0>	PORTH<6>

11.2 Slave Port Modes

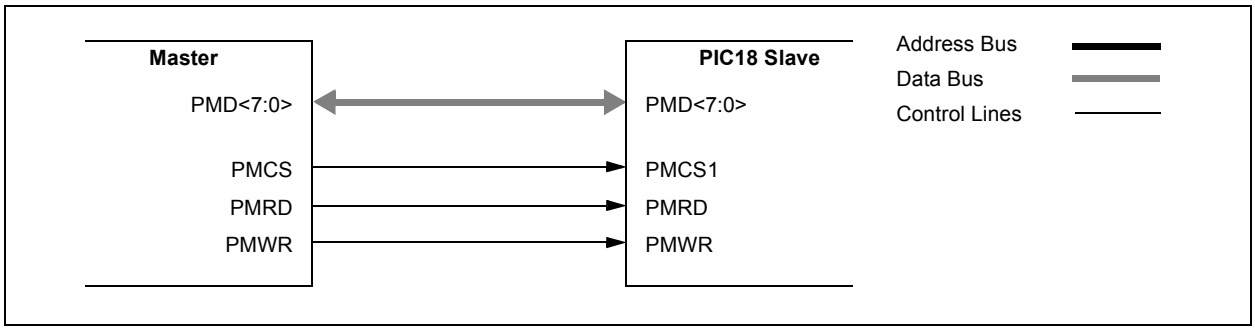
The primary mode of operation for the module is configured using the MODE1:MODE0 bits in the PMMODEH register. The setting affects whether the module acts as a slave or a master and it determines the usage of the control pins.

11.2.1 LEGACY MODE (PSP)

In Legacy mode (PMMODEH<1:0> = 00 and PMPEN = 1), the module is configured as a Parallel Slave Port with the associated enabled module pins dedicated to the module. In this mode, an external device, such as another microcontroller or microprocessor, can asynchronously read and write data using the 8-bit data bus (PMD<7:0>), the read (PMRD), write (PMWR) and chip select (PMCS1) inputs. It acts as a slave on the bus and responds to the read/write control signals.

Figure 11-2 shows the connection of the Parallel Slave Port. When chip select is active and a write strobe occurs (PMCS = 1 and PMWR = 1), the data from PMD<7:0> is captured into the PMDIN1L register.

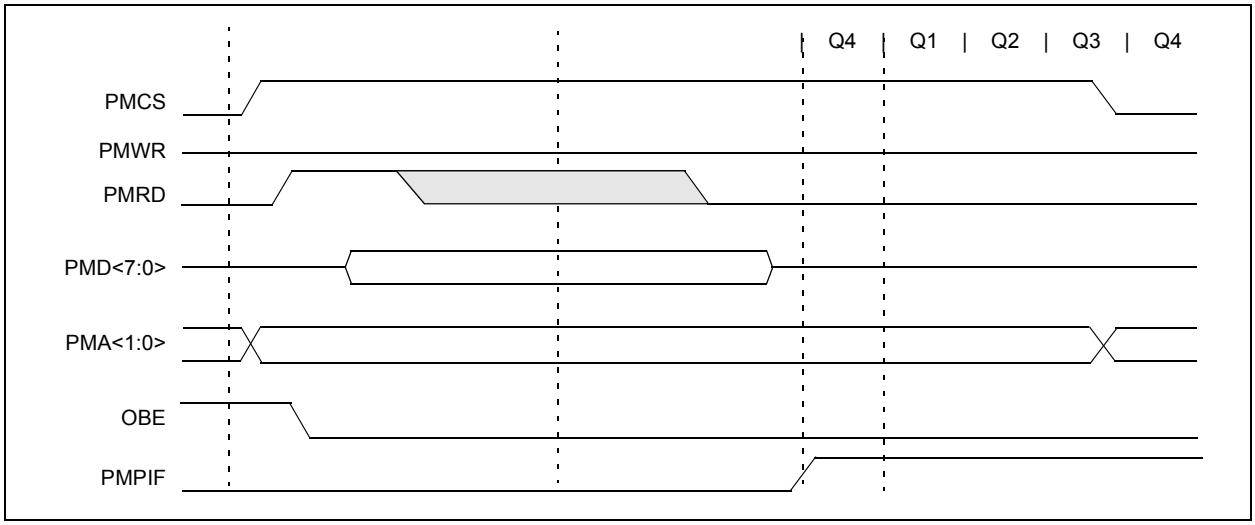
FIGURE 11-2: LEGACY PARALLEL SLAVE PORT EXAMPLE



11.2.5.1 READ FROM SLAVE PORT

When chip select is active and a read strobe occurs (PMCS = 1 and PMRD = 1), the data from one of the four output bytes is presented onto PMD<7:0>. Which byte is read depends on the 2-bit address placed on ADDR[1:0]. Table 11-2 shows the corresponding output registers and their associated address. When an output buffer is read, the corresponding OBxE bit is set. The OBxE flag bit is set when all the buffers are empty. If any buffer is already empty, OBxE = 1, the next read to that buffer will generate an OBUF event.

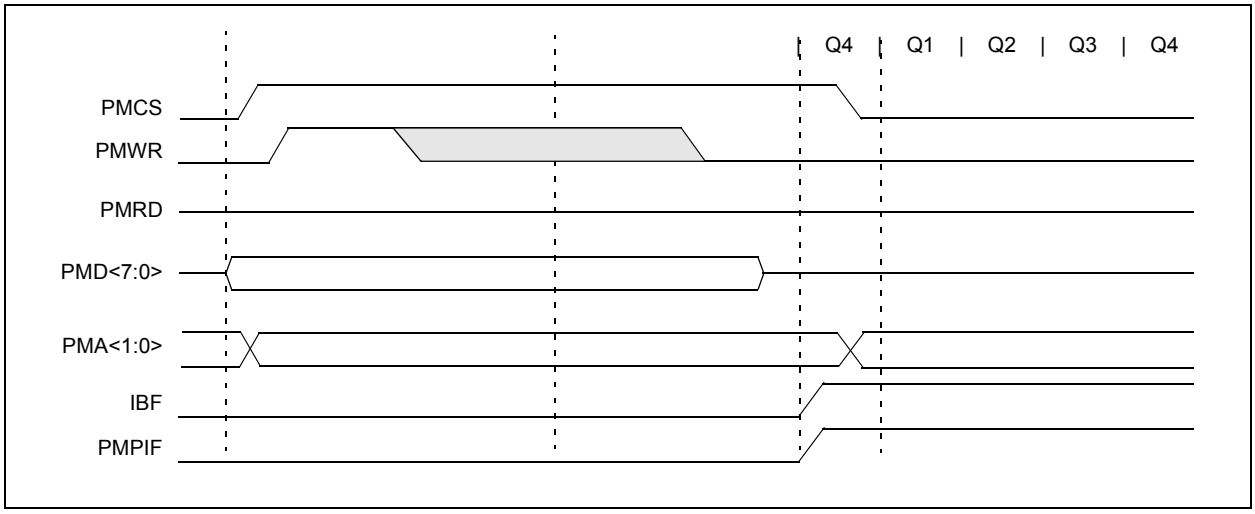
FIGURE 11-7: PARALLEL SLAVE PORT READ WAVEFORMS



11.2.5.2 WRITE TO SLAVE PORT

When chip select is active and a write strobe occurs (PMCS = 1 and PMWR = 1), the data from PMD<7:0> is captured into one of the four input buffer bytes. Which byte is written depends on the 2-bit address placed on ADDRL[1:0]. Table 11-2 shows the corresponding input registers and their associated address. When an input buffer is written, the corresponding IBxF bit is set. The IBF flag bit is set when all the buffers are written. If any buffer is already written (IBxF = 1), the next write strobe to that buffer will generate an OBUF event and the byte will be discarded.

FIGURE 11-8: PARALLEL SLAVE PORT WRITE WAVEFORMS



11.3.5 CHIP SELECT FEATURES

Up to two chip select lines, PMCS1 and PMCS2, are available for the Master modes of the PMP. The two chip select lines are multiplexed with the Most Significant bits of the address bus (PMADDRH<6> and PMADDRH<7>). When a pin is configured as a chip select, it is not included in any address auto-increment/decrement. The function of the chip select signals is configured using the chip select function bits (PMCONL<7:6>).

11.3.6 AUTO-INCREMENT/DECREMENT

While the module is operating in one of the Master modes, the INCM bits (PMMODEH<3:4>) control the behavior of the address value. The address can be made to automatically increment or decrement after each read and write operation. The address increments once each operation is completed and the BUSY bit goes to '0'. If the chip select signals are disabled and configured as address bits, the bits will participate in the increment and decrement operations; otherwise, the CS2 and CS1 bit values will be unaffected.

11.3.7 WAIT STATES

In Master mode, the user has control over the duration of the read, write and address cycles by configuring the module wait states. Three portions of the cycle, the beginning, middle and end, are configured using the corresponding WAITBx, WAITMx and WAITEx bits in the PMMODEL register.

The WAITB bits (PMMODEL<7:6>) set the number of wait cycles for the data setup prior to the PMRD/PMWT strobe in Mode 10, or prior to the PMENB strobe in Mode 11. The WAITM bits (PMMODEL<5:2>) set the number of wait cycles for the PMRD/PMWT strobe in Mode 10, or for the PMENB strobe in Mode 11. When this wait state setting is 0 then WAITB and WAITE have no effect. The WAITE bits (PMMODEL<1:0>) define the number of wait cycles for the data hold time after the PMRD/PMWT strobe in Mode 10, or after the PMENB strobe in Mode 11.

11.3.8 READ OPERATION

To perform a read on the Parallel Master Port, the user reads the PMDIN1L register. This causes the PMP to output the desired values on the chip select lines and the address bus. Then the read line (PMRD) is strobed. The read data is placed into the PMDIN1L register.

If the 16-bit mode is enabled (MODE16 = 1), the read of the low byte of the PMDIN1L register will initiate two bus reads. The first read data byte is placed into the PMDIN1L register, and the second read data is placed into the PMDIN1H.

Note that the read data obtained from the PMDIN1L register is actually the read value from the previous read operation. Hence, the first user read will be a dummy read to initiate the first bus read and fill the read register. Also, the requested read value will not be ready until after the BUSY bit is observed low. Thus, in a back-to-back read operation, the data read from the register will be the same for both reads. The next read of the register will yield the new value.

11.3.9 WRITE OPERATION

To perform a write onto the parallel bus, the user writes to the PMDIN1L register. This causes the module to first output the desired values on the chip select lines and the address bus. The write data from the PMDIN1L register is placed onto the PMD<7:0> data bus. Then the write line (PMWR) is strobed. If the 16-bit mode is enabled (MODE16 = 1), the write to the PMDIN1L register will initiate two bus writes. First write will consist of the data contained in PMDIN1L and the second write will contain the PMDIN1H.

11.3.10 PARALLEL MASTER PORT STATUS

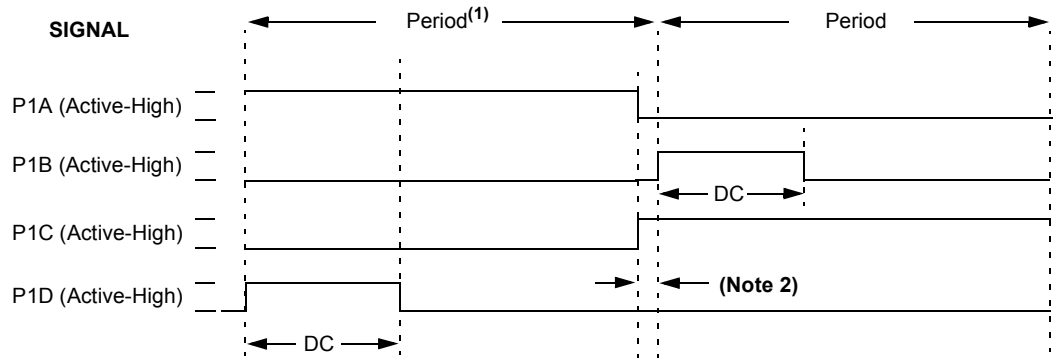
11.3.10.1 The BUSY Bit

In addition to the PMP interrupt, a BUSY bit is provided to indicate the status of the module. This bit is only used in Master mode. While any read or write operation is in progress, the BUSY bit is set for all but the very last CPU cycle of the operation. In effect, if a single-cycle read or write operation is requested, the BUSY bit will never be active. This allows back-to-back transfers. While the bit is set, any request by the user to initiate a new operation will be ignored (i.e., writing or reading the lower byte of the PMDIN1L register will not initiate either a read nor a write).

11.3.10.2 INTERRUPTS

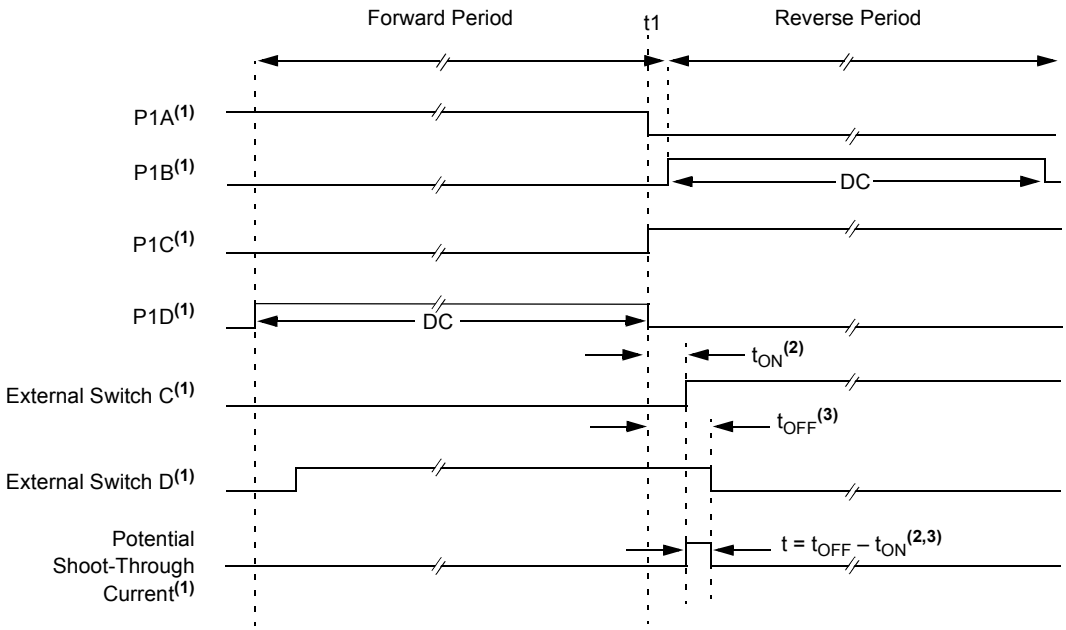
When the PMP module interrupt is enabled for Master mode, the module will interrupt on every completed read or write cycle; otherwise, the BUSY bit is available to query the status of the module.

FIGURE 18-8: PWM DIRECTION CHANGE



Note 1: The direction bit in the ECCP1 Control register (CCP1CON<7>) is written at any time during the PWM cycle.
2: When changing directions, the P1A and P1C signals switch before the end of the current PWM cycle at intervals of 4 TOSC, 16 TOSC or 64 TOSC, depending on the Timer2 prescaler value. The modulated P1B and P1D signals are inactive at this time.

FIGURE 18-9: PWM DIRECTION CHANGE AT NEAR 100% DUTY CYCLE



Note 1: All signals are shown as active-high.
2: t_{ON} is the turn-on delay of power switch QC and its driver.
3: t_{OFF} is the turn-off delay of power switch QD and its driver.

19.4.4.5 Clock Synchronization and the CKP bit

When the CKP bit is cleared, the SCLx output is forced to '0'. However, clearing the CKP bit will not assert the SCLx output low until the SCLx output is already sampled low. Therefore, the CKP bit will not assert the SCLx line until an external I^2C master device has already asserted the SCLx line. The SCLx output will remain low until the CKP bit is set and all other devices on the I^2C bus have deasserted SCLx. This ensures that a write to the CKP bit will not violate the minimum high time requirement for SCLx (see Figure 19-14).

21.7 A/D Converter Calibration

The A/D Converter in the PIC18F87J10 family of devices includes a self-calibration feature which compensates for any offset generated within the module. The calibration process is automated and is initiated by setting the ADCAL bit (ADCON1<6>). The next time the GO/$\overline{\text{DONE}}$ bit is set, the module will perform a "dummy" conversion (that is, with reading none of the input channels) and store the resulting value internally to compensate for the offset. Thus, subsequent offsets will be compensated. An example of a calibration routine is shown in Example 21-1.

The calibration process assumes that the device is in a relatively steady-state operating condition. If A/D calibration is used, it should be performed after each device Reset or if there are other major changes in operating conditions.

21.8 Operation in Power-Managed Modes

The selection of the automatic acquisition time and A/D conversion clock is determined in part by the clock source and frequency while in a power-managed mode.

If the A/D is expected to operate while the device is in a power-managed mode, the ACQT2:ACQT0 and ADCS2:ADCS0 bits in ADCON1 should be updated in accordance with the power-managed mode clock that will be used. After the power-managed mode is entered (either of the power-managed Run modes), an A/D acquisition or conversion may be started. Once an acquisition or conversion is started, the device should continue to be clocked by the same power-managed mode clock source until the conversion has been completed. If desired, the device may be placed into the corresponding power-managed Idle mode during the conversion.

If the power-managed mode clock frequency is less than 1 MHz, the A/D RC clock source should be selected.

Operation in the Sleep mode requires the A/D RC clock to be selected. If bits, ACQT2:ACQT0, are set to '000' and a conversion is started, the conversion will be delayed one instruction cycle to allow execution of the SLEEP instruction and entry to Sleep mode. The IDLEN and SCS bits in the OSCCON register must have already been cleared prior to starting the conversion.

EXAMPLE 21-1: SAMPLE A/D CALIBRATION ROUTINE

```
        BSF     WDTCON,ADSHR        ;Enable write/read to the shared SFR
        BCF     ANCON0,PCFG0        ;Make Channel 0 analog
        BCF     WDTCON,ADSHR        ;Disable write/read to the shared SFR
        BSF     ADCON0,ADON         ;Enable A/D module
        BSF     ADCON1,ADCAL        ;Enable Calibration
        BSF     ADCON0,GO           ;Start a dummy A/D conversion
CALIBRATION                         ;
        BTFSC   ADCON0,GO           ;Wait for the dummy conversion to finish
        BRA     CALIBRATION         ;
        BCF     ADCON1,ADCAL        ;Calibration done, turn off calibration enable
                                    ;Proceed with the actual A/D conversion
```

22.5 USB Interrupts

The USB module can generate multiple interrupt conditions. To accommodate all of these interrupt sources, the module is provided with its own interrupt logic structure, similar to that of the microcontroller. USB interrupts are enabled with one set of control registers and trapped with a separate set of flag registers. All sources are funneled into a single USB interrupt request, USBIF (PIR2<4>), in the microcontroller's interrupt logic.

Figure 22-7 shows the interrupt logic for the USB module. There are two layers of interrupt registers in the USB module. The top level consists of overall USB status interrupts; these are enabled and flagged in the UIE and UIR registers, respectively. The second level consists of USB error conditions, which are enabled and flagged in the UEIR and UEIE registers. An interrupt condition in any of these triggers a USB Error Interrupt Flag (UERRIF) in the top level.

Interrupts may be used to trap routine events in a USB transaction. Figure 22-8 shows some common events within a USB frame and their corresponding interrupts.

FIGURE 22-7: USB INTERRUPT LOGIC FUNNEL

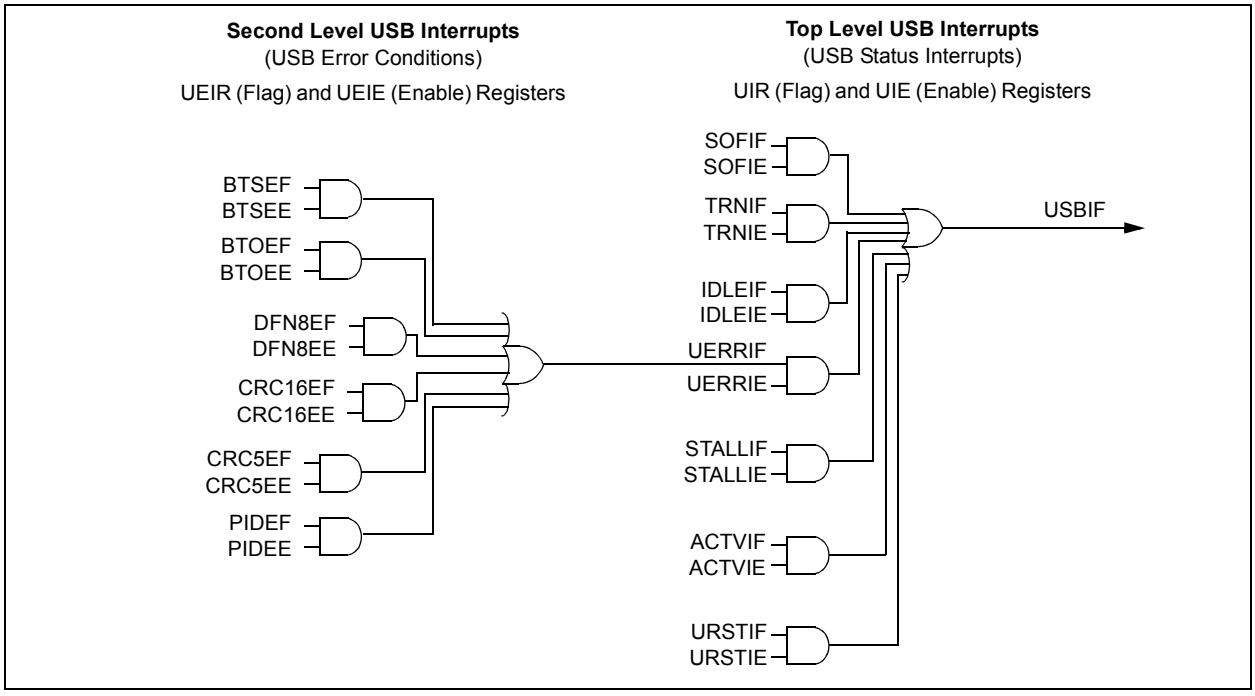

FIGURE 22-8: EXAMPLE OF A USB TRANSACTION AND INTERRUPT EVENTS

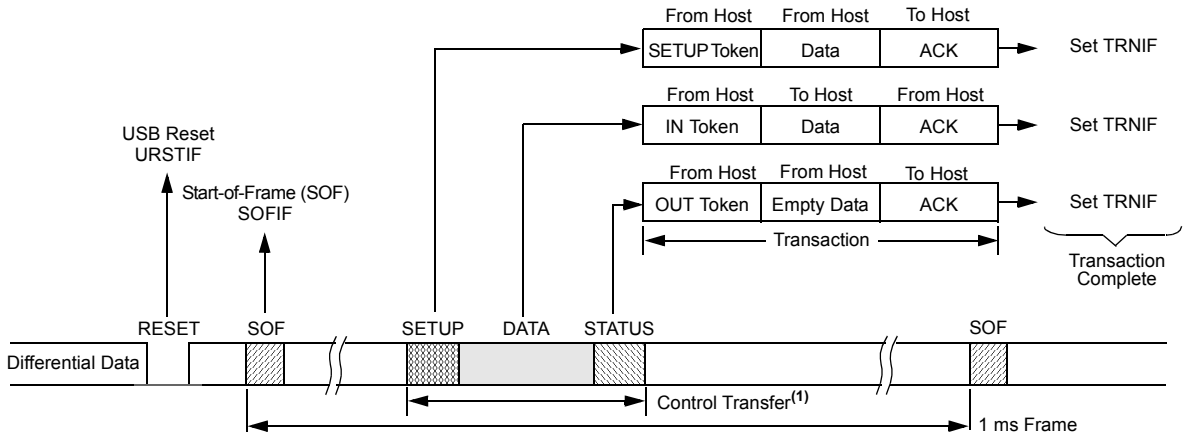

Note 1: The control transfer shown here is only an example showing events that can occur for every transaction. Typical control transfers will spread across multiple frames.

22.5.2 USB INTERRUPT ENABLE REGISTER (UIE)

The USB Interrupt Enable register (Register 22-8) contains the enable bits for the USB status interrupt sources. Setting any of these bits will enable the respective interrupt source in the UIR register.

The values in this register only affect the propagation of an interrupt condition to the microcontroller's interrupt logic. The flag bits are still set by their interrupt conditions, allowing them to be polled and serviced without actually generating an interrupt.

REGISTER 22-8: UIE: USB INTERRUPT ENABLE REGISTER

U-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

0 = Comparator VIN+ > VIN-

25.6 Program Verification and Code Protection

For all devices in the PIC18F87J10 family of devices, the on-chip program memory space is treated as a single block. Code protection for this block is controlled by one Configuration bit, CP0. This bit inhibits external reads and writes to the program memory space. It has no direct effect in normal execution mode.

25.6.1 CONFIGURATION REGISTER PROTECTION

The Configuration registers are protected against untoward changes or reads in two ways. The primary protection is the write-once feature of the Configuration bits which prevents reconfiguration once the bit has been programmed during a power cycle. To safeguard against unpredictable events, Configuration bit changes resulting from individual cell level disruptions (such as ESD events) will cause a parity error and trigger a device Reset. This is seen by the user as a Configuration Mismatch (CM) Reset.

The data for the Configuration registers is derived from the Flash Configuration Words in program memory. When the CP0 bit set, the source data for device configuration is also protected as a consequence.

25.7 In-Circuit Serial Programming

PIC18F87J10 family microcontrollers can be serially programmed while in the end application circuit. This is simply done with two lines for clock and data and three other lines for power, ground and the programming voltage. This allows customers to manufacture boards with unprogrammed devices and then program the microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

25.8 In-Circuit Debugger

When the $\overline{\text{DEBUG}}$ Configuration bit is programmed to a '0', the In-Circuit Debugger functionality is enabled. This function allows simple debugging functions when used with MPLAB® IDE. When the microcontroller has this feature enabled, some resources are not available for general use. Table 25-4 shows which resources are required by the background debugger.

TABLE 25-4: DEBUGGER RESOURCES

I/O pins:	RB6, RB7
Stack:	2 levels
Program Memory:	512 bytes
Data Memory:	10 bytes

26.1.1 STANDARD INSTRUCTION SET

ADDLW **ADD Literal to W**

Syntax: ADDLW k

Operands: $0 \le k \le 255$

Operation: $(W) + k \rightarrow W$

Status Affected: N, OV, C, DC, Z

Encoding:

0000	1111	kkkk	kkkk

Description: The contents of W are added to the 8-bit literal 'k' and the result is placed in W.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Process Data	Write to W

Example: ADDLW 15h

Before Instruction
W = 10h
After Instruction
W = 25h

ADDWF **ADD W to f**

Syntax: ADDWF f {,d {,a}}

Operands: $0 \le f \le 255$
$d \in [0,1]$
$a \in [0,1]$

Operation: $(W) + (f) \rightarrow$ dest

Status Affected: N, OV, C, DC, Z

Encoding:

0010	01da	ffff	ffff

Description: Add W to register 'f'. If 'd' is '0', the result is stored in W. If 'd' is '1', the result is stored back in register 'f' (default).

If 'a' is '0', the Access Bank is selected. If 'a' is '1', the BSR is used to select the GPR bank (default).

If 'a' is '0' and the extended instruction set is enabled, this instruction operates in Indexed Literal Offset Addressing mode whenever $f \le 95$ (5Fh). See **Section 26.2.3 "Byte-Oriented and Bit-Oriented Instructions in Indexed Literal Offset Mode"** for details.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: ADDWF REG, 0, 0

Before Instruction
W = 17h
REG = 0C2h
After Instruction
W = 0D9h
REG = 0C2h

Note: All PIC18 instructions may take an optional label argument preceding the instruction mnemonic for use in symbolic addressing. If a label is used, the instruction format then becomes: {label} instruction argument(s).

SUBLW **Subtract W from Literal**

Syntax: SUBLW k

Operands: $0 \le k \le 255$

Operation: $k - (W) \rightarrow W$

Status Affected: N, OV, C, DC, Z

Encoding:

0000	1000	kkkk	kkkk

Description: W is subtracted from the eight-bit literal 'k'. The result is placed in W.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Process Data	Write to W

Example 1:
```
SUBLW   02h
```
Before Instruction
W = 01h
C = ?
After Instruction
W = 01h
C = 1 ; result is positive
Z = 0
N = 0

Example 2:
```
SUBLW   02h
```
Before Instruction
W = 02h
C = ?
After Instruction
W = 00h
C = 1 ; result is zero
Z = 1
N = 0

Example 3:
```
SUBLW   02h
```
Before Instruction
W = 03h
C = ?
After Instruction
W = FFh ; (2's complement)
C = 0 ; result is negative
Z = 0
N = 1

SUBWF **Subtract W from f**

Syntax: SUBWF f {,d {,a}}

Operands: $0 \le f \le 255$
$d \in [0,1]$
$a \in [0,1]$

Operation: $(f) - (W) \rightarrow dest$

Status Affected: N, OV, C, DC, Z

Encoding:

0101	11da	ffff	ffff

Description: Subtract W from register 'f' (2's complement method). If 'd' is '0', the result is stored in W. If 'd' is '1', the result is stored back in register 'f' (default).

If 'a' is '0', the Access Bank is selected. If 'a' is '1', the BSR is used to select the GPR bank (default).

If 'a' is '0' and the extended instruction set is enabled, this instruction operates in Indexed Literal Offset Addressing mode whenever $f \le 95$ (5Fh). See **Section 26.2.3 "Byte-Oriented and Bit-Oriented Instructions in Indexed Literal Offset Mode"** for details.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example 1:
```
SUBWF   REG, 1, 0
```
Before Instruction
REG = 3
W = 2
C = ?
After Instruction
REG = 1
W = 2
C = 1 ; result is positive
Z = 0
N = 0

Example 2:
```
SUBWF   REG, 0, 0
```
Before Instruction
REG = 2
W = 2
C = ?
After Instruction
REG = 2
W = 0
C = 1 ; result is zero
Z = 1
N = 0

Example 3:
```
SUBWF   REG, 1, 0
```
Before Instruction
REG = 1
W = 2
C = ?
After Instruction
REG = FFh ;(2's complement)
W = 2
C = 0 ; result is negative
Z = 0
N = 1

TBLRD **Table Read**

Syntax: TBLRD (*; *+; *-; +*)

Operands: None

Operation: if TBLRD *,
(Prog Mem (TBLPTR)) → TABLAT,
TBLPTR – No Change;
if TBLRD *+,
(Prog Mem (TBLPTR)) → TABLAT,
(TBLPTR) + 1 → TBLPTR;
if TBLRD *-,
(Prog Mem (TBLPTR)) → TABLAT,
(TBLPTR) – 1 → TBLPTR;
if TBLRD +*,
(TBLPTR) + 1 → TBLPTR,
(Prog Mem (TBLPTR)) → TABLAT

Status Affected: None

Encoding:

0000	0000	0000	10nn nn=0 * =1 *+ =2 *– =3 +*

Description: This instruction is used to read the contents of Program Memory (P.M.). To address the program memory, a pointer called Table Pointer (TBLPTR) is used.

The TBLPTR (a 21-bit pointer) points to each byte in the program memory. TBLPTR has a 2-Mbyte address range.

TBLPTR<0> = 0: Least Significant Byte of Program Memory Word

TBLPTR<0> = 1: Most Significant Byte of Program Memory Word

The TBLRD instruction can modify the value of TBLPTR as follows:

- no change
- post-increment
- post-decrement
- pre-increment

Words: 1

Cycles: 2

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	No operation	No operation	No operation
No operation	No operation (Read Program Memory)	No operation	No operation (Write TABLAT)

TBLRD **Table Read (Continued)**

Example 1:
```
TBLRD  *+ ;
```
Before Instruction
TABLAT = 55h
TBLPTR = 00A356h
MEMORY(00A356h) = 34h
After Instruction
TABLAT = 34h
TBLPTR = 00A357h

Example 2:
```
TBLRD  +* ;
```
Before Instruction
TABLAT = AAh
TBLPTR = 01A357h
MEMORY(01A357h) = 12h
MEMORY(01A358h) = 34h
After Instruction
TABLAT = 34h
TBLPTR = 01A358h

28.2 DC Characteristics: Power-Down and Supply Current PIC18F87J50 Family (Industrial)

PIC18F87J50 Family (Industrial)		Standard Operating Conditions (unless otherwise stated) Operating temperature -40°C ≤ TA ≤ +85°C for industrial				
Param No.	**Device**	**Typ**	**Max**	**Units**	**Conditions**	
	Power-Down Current (IPD)(1)					
	All devices	0.5	1.4	µA	-40°C	VDD = 2.0V(4), VDDCORE = 2.0V (**Sleep** mode)
		0.5	1.4	µA	+25°C	
		5.5	10.2	µA	+85°C	
	All devices	0.6	1.5	µA	-40°C	VDD = 2.5V(4), VDDCORE = 2.5V (**Sleep** mode)
		0.6	1.5	µA	+25°C	
		6.8	12.6	µA	+85°C	
	All devices	2.9	7	µA	-40°C	VDD = 3.3V(5) (**Sleep** mode)
		3.6	7	µA	+25°C	
		9.6	19	µA	+85°C	

Note 1: The power-down current in Sleep mode does not depend on the oscillator type. Power-down current is measured with the part in Sleep mode, with all I/O pins in high-impedance state and tied to VDD or VSS and all features that add delta current disabled (such as WDT, Timer1 oscillator, BOR, etc.).

2: The supply current is mainly a function of operating voltage, frequency and mode. Other factors, such as I/O pin loading and switching rate, oscillator type and circuit, internal code execution pattern and temperature, also have an impact on the current consumption. All features that add delta current are disabled (USB module, WDT, etc.).
The test conditions for all IDD measurements in active operation mode are:
OSC1 = external square wave, from rail-to-rail; all I/O pins tri-stated, pulled to VDD;
$\overline{\text{MCLR}}$ = VDD; WDT disabled unless otherwise specified.

3: Standard, low-cost 32 kHz crystals have an operating temperature range of -10°C to +70°C. Extended temperature crystals are available at a much higher cost.

4: Voltage regulator disabled (ENVREG = 0, tied to VSS).

5: Voltage regulator enabled (ENVREG = 1, tied to VDD), REGSLP = 1.

6: This is the module differential current when the USB module is enabled and clocked at 48 MHz, but with no USB cable attached. When the USB cable is attached or data is being transmitted, the current consumption may be much higher (see **Section 22.6.4 "USB Transceiver Current Consumption"**). During USB Suspend mode (USBEN = 1, SUSPND = 1, bus in Idle state), the USB module current will be dominated by the D+ or D- pull-up resistor. The integrated pull-up resistors use "resistor switching" according to the resistor_ecn supplement to the USB 2.0 specifications, and therefore, may be as low as 900Ω during Idle conditions.

NOTES:
