Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Active
Number of LABs/CLBs	-
Number of Logic Elements/Cells	-
Total RAM Bits	276480
Number of I/O	223
Number of Gates	1500000
Voltage - Supply	1.425V ~ 1.575V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 100°C (TJ)
Package / Case	484-BGA
Supplier Device Package	484-FPBGA (23x23)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/m1afs1500-2fg484i

Embedded Memories

Flash Memory Blocks

The flash memory available in each Fusion device is composed of one to four flash blocks, each 2 Mbits in density. Each block operates independently with a dedicated flash controller and interface. Fusion flash memory blocks combine fast access times (60 ns random access and 10 ns access in Read-Ahead mode) with a configurable 8-, 16-, or 32-bit datapath, enabling high-speed flash operation without wait states. The memory block is organized in pages and sectors. Each page has 128 bytes, with 33 pages comprising one sector and 64 sectors per block. The flash block can support multiple partitions. The only constraint on size is that partition boundaries must coincide with page boundaries. The flexibility and granularity enable many use models and allow added granularity in programming updates.

Fusion devices support two methods of external access to the flash memory blocks. The first method is a serial interface that features a built-in JTAG-compliant port, which allows in-system programmability during user or monitor/test modes. This serial interface supports programming of an AES-encrypted stream. Data protected with security measures can be passed through the JTAG interface, decrypted, and then programmed in the flash block. The second method is a soft parallel interface.

FPGA logic or an on-chip soft microprocessor can access flash memory through the parallel interface. Since the flash parallel interface is implemented in the FPGA fabric, it can potentially be customized to meet special user requirements. For more information, refer to the *CoreCFI Handbook.* The flash memory parallel interface provides configurable byte-wide (×8), word-wide (×16), or dual-word-wide (×32) data-port options. Through the programmable flash parallel interface, the on-chip and off-chip memories can be cascaded for wider or deeper configurations.

The flash memory has built-in security. The user can configure either the entire flash block or the small blocks to protect against unintentional or intrusive attempts to change or destroy the storage contents. Each on-chip flash memory block has a dedicated controller, enabling each block to operate independently.

The flash block logic consists of the following sub-blocks:

- Flash block – Contains all stored data. The flash block contains 64 sectors and each sector contains 33 pages of data.
- Page Buffer – Contains the contents of the current page being modified. A page contains 8 blocks of data.
- Block Buffer – Contains the contents of the last block accessed. A block contains 128 data bits.
- ECC Logic – The flash memory stores error correction information with each block to perform single-bit error correction and double-bit error detection on all data blocks.

User Nonvolatile FlashROM

In addition to the flash blocks, Fusion devices have 1 Kbit of user-accessible, nonvolatile FlashROM on-chip. The FlashROM is organized as 8×128-bit pages. The FlashROM can be used in diverse system applications:

- Internet protocol addressing (wireless or fixed)
- System calibration settings
- Device serialization and/or inventory control
- Subscription-based business models (for example, set-top boxes)
- Secure key storage for communications algorithms protected by security
- Asset management/tracking
- Date stamping
- Version management

The FlashROM is written using the standard IEEE 1532 JTAG programming interface. Pages can be individually programmed (erased and written). On-chip AES decryption can be used selectively over public networks to load data such as security keys stored in the FlashROM for a user design.

The FlashROM can be programmed (erased and written) via the JTAG programming interface, and its contents can be read back either through the JTAG programming interface or via direct FPGA core addressing.

RC Oscillator

The RC oscillator is an on-chip free-running clock source generating a 100 MHz clock. It can be used as a source clock for both on-chip and off-chip resources. When used in conjunction with the Fusion PLL and CCC circuits, the RC oscillator clock source can be used to generate clocks of varying frequency and phase.

The Fusion RC oscillator is very accurate at ±1% over commercial temperature ranges and and ±3% over industrial temperature ranges. It is an automated clock, requiring no setup or configuration by the user. It requires only that the power and GNDOSC pins be connected; no external components are required. The RC oscillator can be used to drive either a PLL or another internal signal.

RC Oscillator Characteristics

Table 2-9 • **Electrical Characteristics of RC Oscillator**

Parameter	Description	Conditions	Min.	Typ.	Max.	Units
F_{RC}	Operating Frequency			100		MHz
	Accuracy	Temperature: 0°C to 85°C Voltage: 3.3 V ± 5%		1		%
		Temperature: –40°C to 125°C Voltage: 3.3 V ± 5%		3		%
	Output Jitter	Period Jitter (at 5 k cycles)		100		ps
		Cycle–Cycle Jitter (at 5 k cycles)		100		ps
		Period Jitter (at 5 k cycles) with 1 KHz / 300 mV peak-to-peak noise on power supply		150		ps
		Cycle–Cycle Jitter (at 5 k cycles) with 1 KHz / 300 mV peak-to-peak noise on power supply		150		ps
	Output Duty Cycle			50		%
I_{DYNRC}	Operating Current			1		mA

The NGMUX macro is simplified to show the two clock options that have been selected by the GLMUXCFG[1:0] bits. Figure 2-25 illustrates the NGMUX macro. During design, the two clock sources are connected to CLK0 and CLK1 and are controlled by GLMUXSEL[1:0] to determine which signal is to be passed through the MUX.

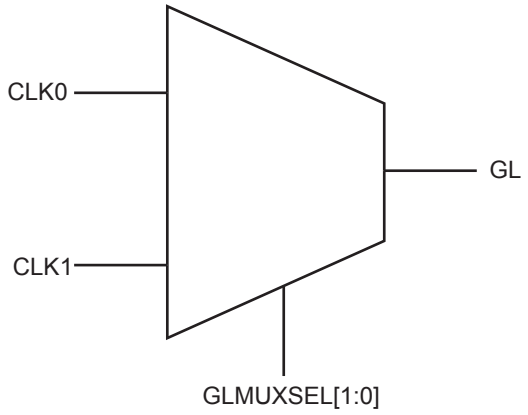

Figure 2-25 • **NGMUX Macro**

The sequence of switching between two clock sources (from CLK0 to CLK1) is as follows (Figure 2-26):

- GLMUXSEL[1:0] transitions to initiate a switch.
- GL drives one last complete CLK0 positive pulse (i.e., one rising edge followed by one falling edge).
- From that point, GL stays Low until the second rising edge of CLK1 occurs.
- At the second CLK1 rising edge, GL will begin to continuously deliver the CLK1 signal.
- Minimum t_{sw} = 0.05 ns at 25°C (typical conditions)

For examples of NGMUX operation, refer to the *Fusion FPGA Fabric User Guide*.

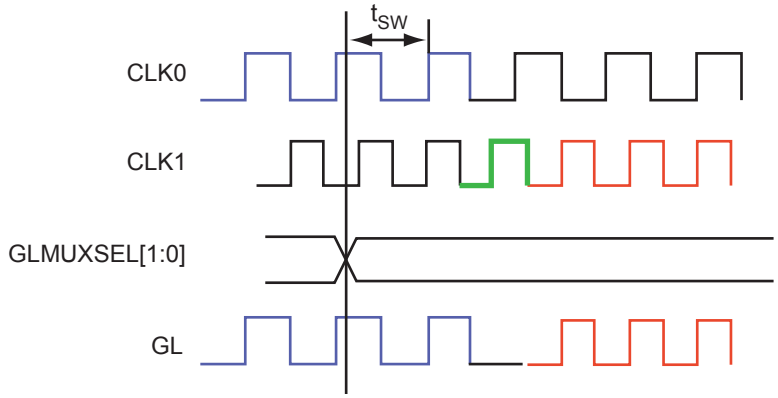

Figure 2-26 • **NGMUX Waveform**

***Table 2-19* • Flash Memory Block Pin Names (continued)**

Interface Name	Width	Direction	Description
STATUS[1:0]	2	Out	Status of the last operation completed: 00: Successful completion 01: Read-/Unprotect-Page: single error detected and corrected Write: operation addressed a write-protected page Erase-Page: protection violation Program: Page Buffer is unmodified Protection violation 10: Read-/Unprotect-Page: two or more errors detected 11: Write: attempt to write to another page before programming current page Erase-Page/Program: page write count has exceeded the 10-year retention threshold
UNPROTECTPAGE	1	In	When asserted, the page addressed is copied into the Page Buffer and the Page Buffer is made writable.
WD[31:0]	32	In	Write data
WEN	1	In	When asserted, stores WD in the page buffer.

All flash memory block input signals are active high, except for RESET.

Analog Block

With the Fusion family, Microsemi has introduced the world's first mixed-mode FPGA solution. Supporting a robust analog peripheral mix, Fusion devices will support a wide variety of applications. It is this Analog Block that separates Fusion from all other FPGA solutions on the market today.

By combining both flash and high-speed CMOS processes in a single chip, these devices offer the best of both worlds. The high-performance CMOS is used for building RAM resources. These high-performance structures support device operation up to 350 MHz. Additionally, the advanced Microsemi 0.13 µm flash process incorporates high-voltage transistors and a high-isolation, triple-well process. Both of these are suited for the flash-based programmable logic and nonvolatile memory structures.

High-voltage transistors support the integration of analog technology in several ways. They aid in noise immunity so that the analog portions of the chip can be better isolated from the digital portions, increasing analog accuracy. Because they support high voltages, Microsemi flash FPGAs can be connected directly to high-voltage input signals, eliminating the need for external resistor divider networks, reducing component count, and increasing accuracy. By supporting higher internal voltages, the Microsemi advanced flash process enables high dynamic range on analog circuitry, increasing precision and signal–noise ratio. Microsemi flash FPGAs also drive high-voltage outputs, eliminating the need for external level shifters and drivers.

The unique triple-well process enables the integration of high-performance analog features with increased noise immunity and better isolation. By increasing the efficiency of analog design, the triple-well process also enables a smaller overall design size, reducing die size and cost.

The Analog Block consists of the Analog Quad I/O structure, RTC (for details refer to the "Real-Time Counter System" section on page 2-31), ADC, and ACM. All of these elements are combined in the single Analog Block macro, with which the user implements this functionality (Figure 2-64).

The Analog Block needs to be reset/reinitialized after the core powers up or the device is programmed. An external reset/initialize signal, which can come from the internal voltage regulator when it powers up, must be applied.

INL – Integral Non-Linearity

INL is the deviation of an actual transfer function from a straight line. After nullifying offset and gain errors, the straight line is either a best-fit straight line or a line drawn between the end points of the transfer function (Figure 2-85).

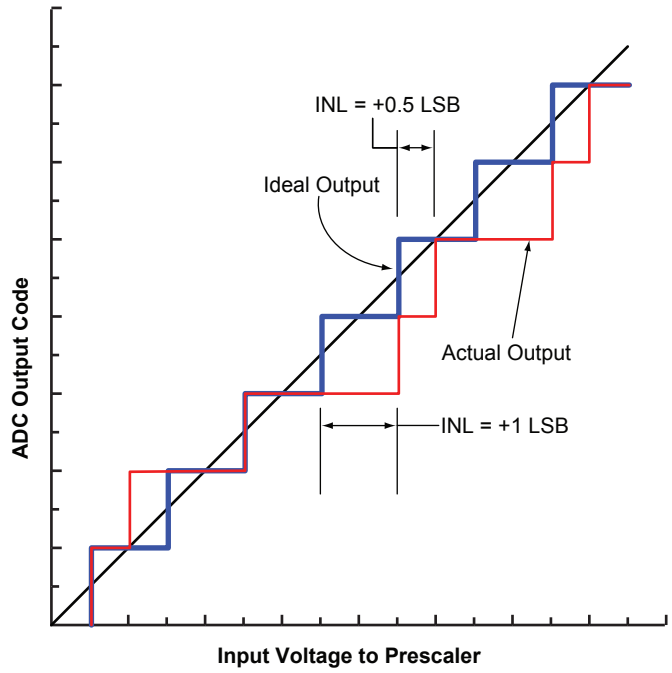

Figure 2-85 • **Integral Non-Linearity (INL)**

LSB – Least Significant Bit

In a binary number, the LSB is the least weighted bit in the group. Typically, the LSB is the furthest right bit. For an ADC, the weight of an LSB equals the full-scale voltage range of the converter divided by 2^N, where N is the converter's resolution.

EQ 13 shows the calculation for a 10-bit ADC with a unipolar full-scale voltage of 2.56 V:

$$1\ \text{LSB} = (2.56\ \text{V} / 2^{10}) = 2.5\ \text{mV}$$

EQ 13

No Missing Codes

An ADC has no missing codes if it produces all possible digital codes in response to a ramp signal applied to the analog input.

ADC Interface Timing

Table 2-48 • ADC Interface Timing
Commercial Temperature Range Conditions: T_J = 70°C, Worst-Case VCC = 1.425 V

Parameter	Description	–2	–1	Std.	Units
t_{SUMODE}	Mode Pin Setup Time	0.56	0.64	0.75	ns

Notes:

1. *VRSM is the maximum voltage drop across the current sense resistor.*
2. *Analog inputs used as digital inputs can tolerate the same voltage limits as the corresponding analog pad. There is no reliability concern on digital inputs as long as VIND does not exceed these limits.*
3. *VIND is limited to VCC33A + 0.2 to allow reaching 10 MHz input frequency.*
4. *An averaging of 1,024 samples (LPF setting in Analog System Builder) is required and the maximum capacitance allowed across the AT pins is 500 pF.*
5. *The temperature offset is a fixed positive value.*
6. *The high current mode has a maximum power limit of 20 mW. Appropriate current limit resistors must be used, based on voltage on the pad.*
7. *When using SmartGen Analog System Builder, CalibIP is required to obtain specified offset. For further details on CalibIP, refer to the "Temperature, Voltage, and Current Calibration in Fusion FPGAs" chapter of the* Fusion FPGA Fabric User Guide.

I/O Software Support

In the Fusion development software, default settings have been defined for the various I/O standards supported. Changes can be made to the default settings via the use of attributes; however, not all I/O attributes are applicable for all I/O standards. Table 2-84 and Table 2-85 list the valid I/O attributes that can be manipulated by the user for each I/O standard.

Single-ended I/O standards in Fusion support up to five different drive strengths.

Table 2-84 • **Fusion Standard and Advanced I/O Attributes vs. I/O Standard Applications**

I/O Standards	SLEW (output only)	OUT_DRIVE (output only)	SKEW (all macros with OE)*	RES_PULL	OUT_LOAD (output only)	COMBINE_REGISTER

BLVDS/M-LVDS

Bus LVDS (BLVDS) and Multipoint LVDS (M-LVDS) specifications extend the existing LVDS standard to high-performance multipoint bus applications. Multidrop and multipoint bus configurations can contain any combination of drivers, receivers, and transceivers. Microsemi LVDS drivers provide the higher drive current required by BLVDS and M-LVDS to accommodate the loading. The driver requires series terminations for better signal quality and to control voltage swing. Termination is also required at both ends of the bus, since the driver can be located anywhere on the bus. These configurations can be implemented using TRIBUF_LVDS and BIBUF_LVDS macros along with appropriate terminations. Multipoint designs using Microsemi LVDS macros can achieve up to 200 MHz with a maximum of 20 loads. A sample application is given in Figure 2-135. The input and output buffer delays are available in the LVDS section in Table 2-171.

Example: For a bus consisting of 20 equidistant loads, the following terminations provide the required differential voltage, in worst-case industrial operating conditions at the farthest receiver: R_S = 60 Ω and R_T = 70 Ω, given Z_0 = 50 Ω (2") and Z_{stub} = 50 Ω (~1.5").
