Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

Details	
Product Status	Active
Number of LABs/CLBs	-
Number of Logic Elements/Cells	-
Total RAM Bits	110592
Number of I/O	172
Number of Gates	600000
Voltage - Supply	1.425V ~ 1.575V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 85°C (TJ)
Package / Case	484-BGA
Supplier Device Package	484-FPBGA (23x23)

Specifying I/O States During Programming

You can modify the I/O states during programming in FlashPro. In FlashPro, this feature is supported for PDB files generated from Designer v8.5 or greater. See the *FlashPro User Guide* for more information.

Note: PDB files generated from Designer v8.1 to Designer v8.4 (including all service packs) have limited display of Pin Numbers only.

The I/Os are controlled by the JTAG Boundary Scan register during programming, except for the analog pins (AC, AT and AV). The Boundary Scan register of the AG pin can be used to enable/disable the gate driver in software v9.0.

1. Load a PDB from the FlashPro GUI. You must have a PDB loaded to modify the I/O states during programming.
2. From the FlashPro GUI, click **PDB Configuration**. A FlashPoint – Programming File Generator window appears.
3. Click the **Specify I/O States During Programming** button to display the Specify I/O States During Programming dialog box.
4. Sort the pins as desired by clicking any of the column headers to sort the entries by that header. Select the I/Os you wish to modify (Figure 1-3).
5. Set the I/O Output State. You can set Basic I/O settings if you want to use the default I/O settings for your pins, or use Custom I/O settings to customize the settings for each pin. Basic I/O state settings:

   1 – I/O is set to drive out logic High

   0 – I/O is set to drive out logic Low

   Last Known State – I/O is set to the last value that was driven out prior to entering the programming mode, and then held at that value during programming

   Z -Tri-State: I/O is tristated

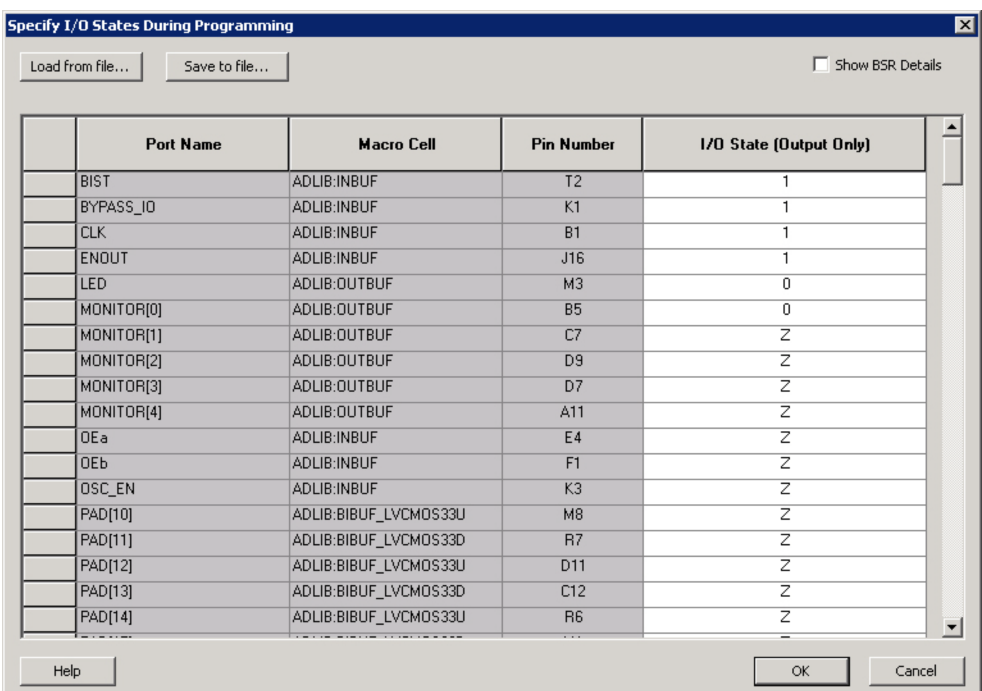

Figure 1-3 • **I/O States During Programming Window**

6. Click **OK** to return to the FlashPoint – Programming File Generator window.

I/O States During programming are saved to the ADB and resulting programming files after completing programming file generation.

Global Resources (VersaNets)

Fusion devices offer powerful and flexible control of circuit timing through the use of analog circuitry. Each chip has six CCCs. The west CCC also contains a PLL core. In the two larger devices (AFS600 and AFS1500), the west and the east CCCs each contain a PLL. The PLLs include delay lines, a phase shifter (0°, 90°, 180°, 270°), and clock multipliers/dividers. Each CCC has all the circuitry needed for the selection and interconnection of inputs to the VersaNet global network. The east and west CCCs each have access to three VersaNet global lines on each side of the chip (six lines total). The CCCs at the four corners each have access to three quadrant global lines on each quadrant of the chip.

Advantages of the VersaNet Approach

One of the architectural benefits of Fusion is the set of powerful and low-delay VersaNet global networks. Fusion offers six chip (main) global networks that are distributed from the center of the FPGA array (Figure 2-11). In addition, Fusion devices have three regional globals (quadrant globals) in each of the four chip quadrants. Each core VersaTile has access to nine global network resources: three quadrant and six chip (main) global networks. There are a total of 18 global networks on the device. Each of these networks contains spines and ribs that reach all VersaTiles in all quadrants (Figure 2-12 on page 2-12). This flexible VersaNet global network architecture allows users to map up to 180 different internal/external clocks in a Fusion device. Details on the VersaNet networks are given in Table 2-4 on page 2-12. The flexibility of the Fusion VersaNet global network allows the designer to address several design requirements. User applications that are clock-resource-intensive can easily route external or gated internal clocks using VersaNet global routing networks. Designers can also drastically reduce delay penalties and minimize resource usage by mapping critical, high-fanout nets to the VersaNet global network.

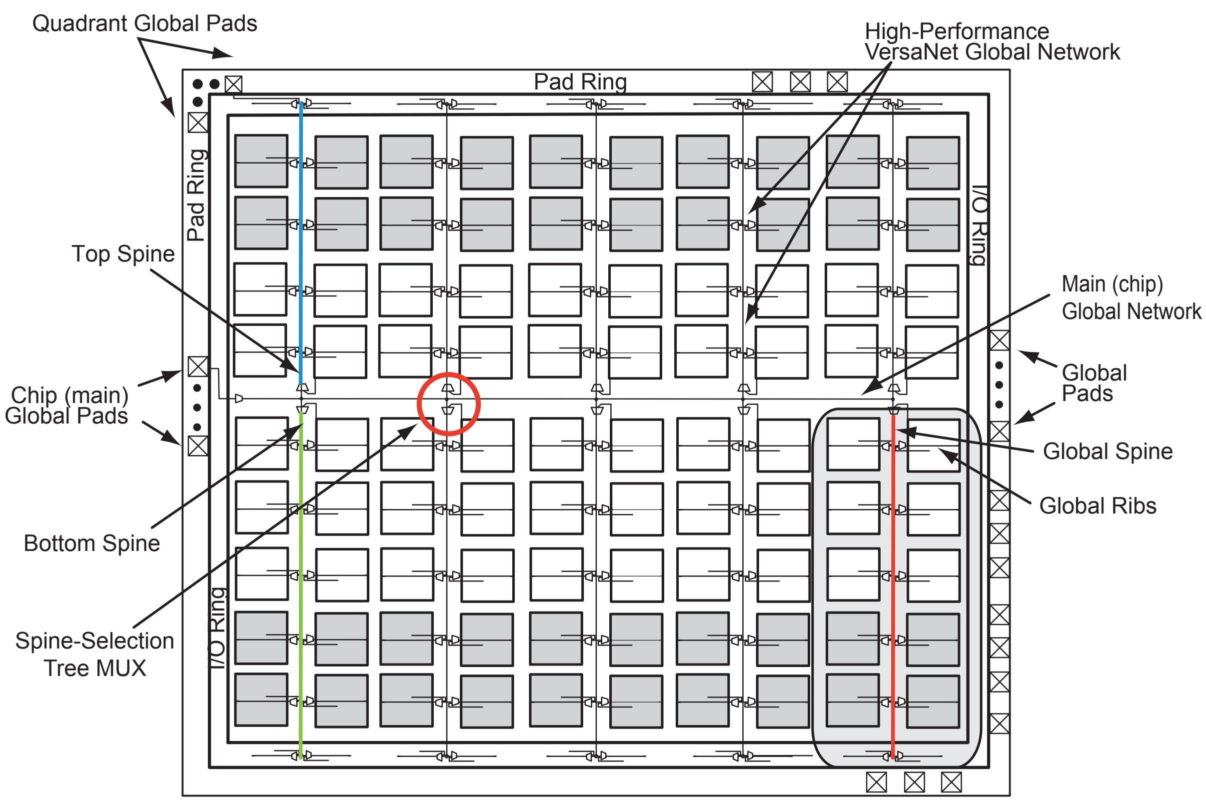

***Figure 2-11* • Overview of Fusion VersaNet Global Network**

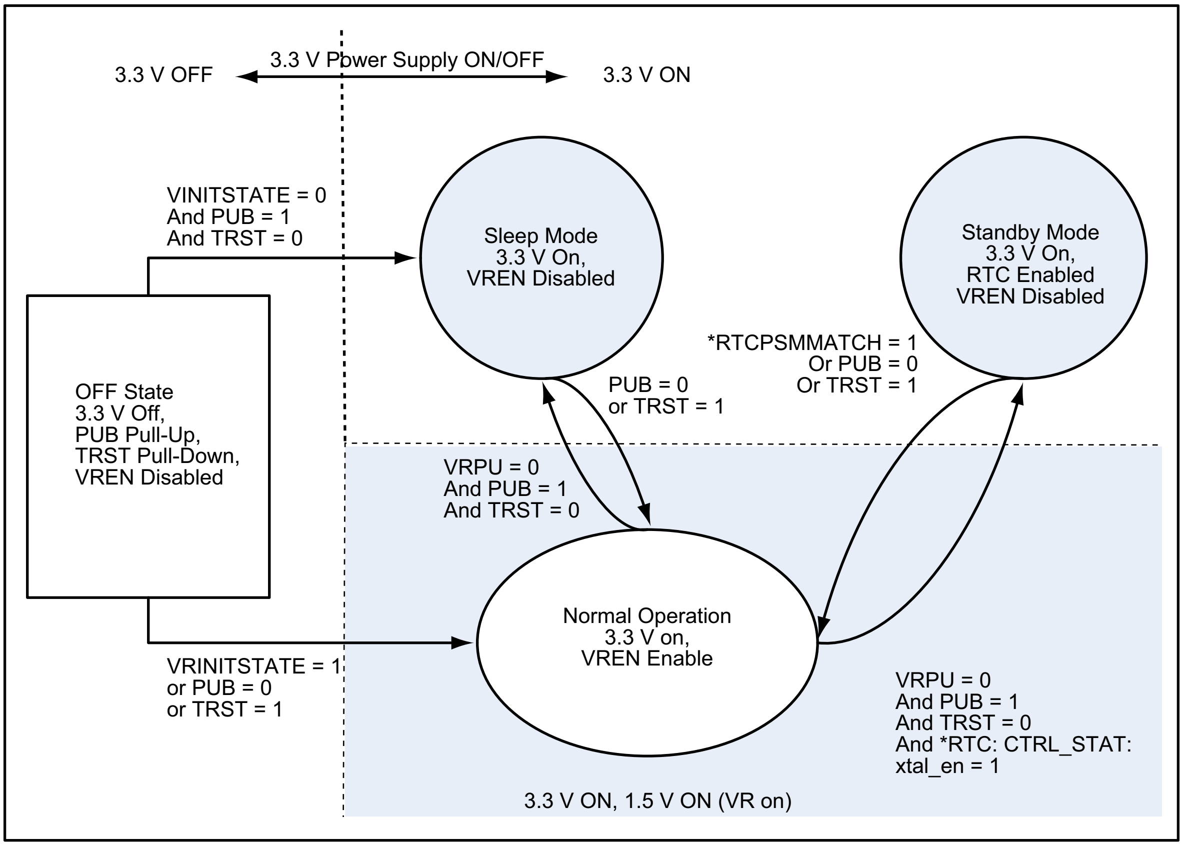

Note: * *To enter and exit standby mode without any external stimulus on PUB or TRST, the vr_en_mat in the CTRL_STAT register must also be set to 1, so that RTCPSMMATCH will assert when a match occurs; hence the device exits standby mode.*

***Figure 2-31* • State Diagram for All Different Power Modes**

When TRST is 1 or PUB is 0, the 1.5 V voltage regulator is always ON, putting the Fusion device in normal operation at all times. Therefore, when the JTAG port is not in reset, the Fusion device cannot enter sleep mode or standby mode.

To enter standby mode, the Fusion device must first power-up into normal operation. The RTC is enabled through the RTC Control/Status Register described in the "Real-Time Counter (part of AB macro)" section on page 2-33. A match value corresponding to the wake-up time is loaded into the Match Register. The 1.5 V voltage regulator is disabled by setting VRPU to 0 to allow the Fusion device to enter standby mode, when the 1.5 V supply is off but the RTC remains on.

The following signals are used to configure the FIFO4K18 memory element.

WW and RW

These signals enable the FIFO to be configured in one of the five allowable aspect ratios (Table 2-33).

***Table 2-33* • Aspect Ratio Settings for WW[2:0]**

WW2, WW1, WW0	RW2, RW1, RW0	D×W
000	000	4k×1
001	001	2k×2
010	010	1k×4
011	011	512×9
100	100	256×18
101, 110, 111	101, 110, 111	Reserved

WBLK and RBLK

These signals are active low and will enable the respective ports when Low. When the RBLK signal is High, the corresponding port's outputs hold the previous value.

WEN and REN

Read and write enables. WEN is active low and REN is active high by default. These signals can be configured as active high or low.

WCLK and RCLK

These are the clock signals for the synchronous read and write operations. These can be driven independently or with the same driver.

RPIPE

This signal is used to specify pipelined read on the output. A Low on RPIPE indicates a nonpipelined read, and the data appears on the output in the same clock cycle. A High indicates a pipelined read, and data appears on the output in the next clock cycle.

RESET

This active low signal resets the output to zero when asserted. It resets the FIFO counters. It also sets all the RD pins Low, the FULL and AFULL pins Low, and the EMPTY and AEMPTY pins High (Table 2-34).

***Table 2-34* • Input Data Signal Usage for Different Aspect Ratios**

D×W	WD/RD Unused
4k×1	WD[17:1], RD[17:1]
2k×2	WD[17:2], RD[17:2]
1k×4	WD[17:4], RD[17:4]
512×9	WD[17:9], RD[17:9]
256×18	–

WD

This is the input data bus and is 18 bits wide. Not all 18 bits are valid in all configurations. When a data width less than 18 is specified, unused higher-order signals must be grounded (Table 2-34).

RD

This is the output data bus and is 18 bits wide. Not all 18 bits are valid in all configurations. Like the WD bus, high-order bits become unusable if the data width is less than 18. The output data on unused pins is undefined (Table 2-34).

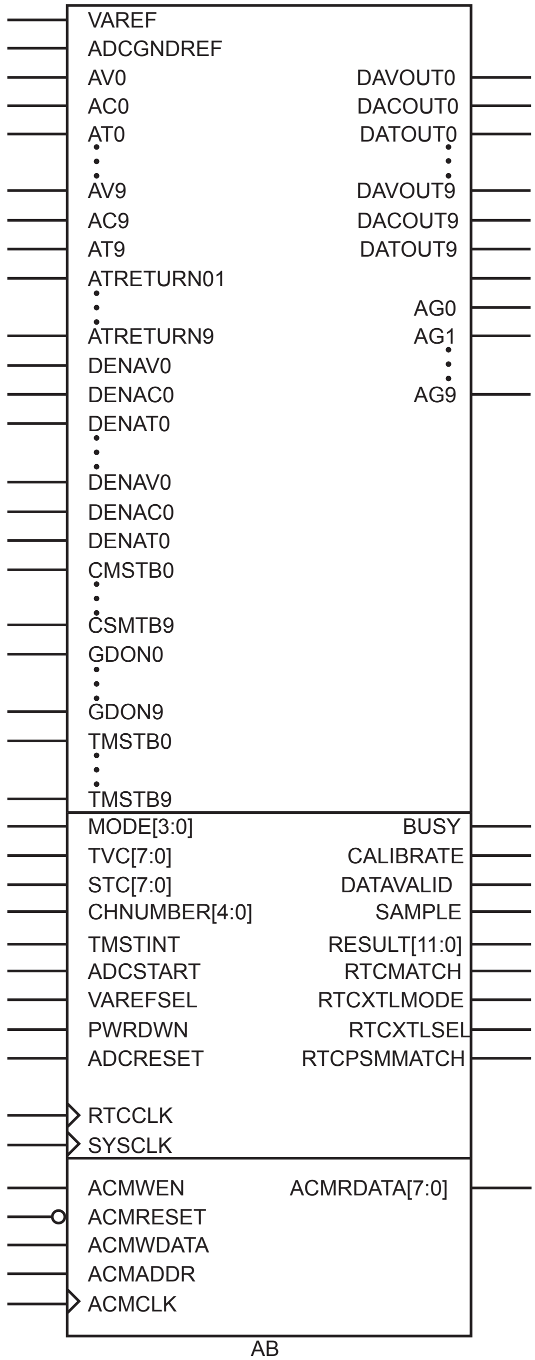

Figure 2-64 • **Analog Block Macro**

Intra-Conversion

Performing a conversion during power-up calibration is possible but should be avoided, since the performance is not guaranteed, as shown in Table 2-49 on page 2-117. This is described as intra-conversion. Figure 2-92 on page 2-113 shows intra-conversion, (conversion that starts during power-up calibration).

Injected Conversion

A conversion can be interrupted by another conversion. Before the current conversion is finished, a second conversion can be started by issuing a pulse on signal ADCSTART. When a second conversion is issued before the current conversion is completed, the current conversion would be dropped and the ADC would start the second conversion on the rising edge of the SYSCLK. This is known as injected conversion. Since the ADC is synchronous, the minimum time to issue a second conversion is two clock cycles of SYSCLK after the previous one. Figure 2-93 on page 2-113 shows injected conversion, (conversion that starts before a previously started conversion is finished). The total time for calibration still remains 3,840 ADCCLK cycles.

ADC Example

This example shows how to choose the correct settings to achieve the fastest sample time in 10-bit mode for a system that runs at 66 MHz. Assume the acquisition times defined in Table 2-44 on page 2-108 for 10-bit mode, which gives 0.549 µs as a minimum hold time.

The period of SYSCLK: t_{SYSCLK} = 1/66 MHz = 0.015 µs

Choosing TVC between 1 and 33 will meet the maximum and minimum period for the ADCCLK requirement. A higher TVC leads to a higher ADCCLK period.

The minimum TVC is chosen so that $t_{distrib}$ and $t_{post\text{-}cal}$ can be run faster. The period of ADCCLK with a TVC of 1 can be computed by EQ 24.

$$t_{ADCCLK} = 4 \times (1 + TVC) \times t_{SYSCLK} = 4 \times (1 + 1) \times 0.015\ \mu s = 0.12\ \mu s$$

EQ 24

The STC value can now be computed by using the minimum sample/hold time from Table 2-44 on page 2-108, as shown in EQ 25.

$$STC = \frac{t_{sample}}{t_{ADCCLK}} - 2 = \frac{0.549\ \mu s}{0.12\ \mu s} - 2 = 4.575 - 2 = 2.575$$

EQ 25

You must round up to 3 to accommodate the minimum sample time requirement. The actual sample time, t_{sample}, with an STC of 3, is now equal to 0.6 µs, as shown in EQ 26

$$t_{sample} = (2 + STC) \times t_{ADCCLK} = (2 + 3) \times t_{ADCCLK} = 5 \times 0.12\ \mu s = 0.6\ \mu s$$

EQ 26

Microsemi recommends post-calibration for temperature drift over time, so post-calibration is enabled.

The post-calibration time, $t_{post\text{-}cal}$, can be computed by EQ 27. The post-calibration time is 0.24 µs.

$$t_{post\text{-}cal} = 2 \times t_{ADCCLK} = 0.24\ \mu s$$

EQ 27

The distribution time, $t_{distrib}$, is equal to 1.2 µs and can be computed as shown in EQ 28 (N is number of bits, referring back to EQ 8 on page 2-94).

$$t_{distrib} = N \times t_{ADCCLK} = 10 \times 0.12 = 1.2\ \mu s$$

EQ 28

The total conversion time can now be summated, as shown in EQ 29 (referring to EQ 23 on page 2-109).

$$t_{sync\_read} + t_{sample} + t_{distrib} + t_{post\text{-}cal} + tsync\_write = (0.015 + 0.60 + 1.2 + 0.24 + 0.015)\ \mu s = 2.07\ \mu s$$

EQ 29

3.3 V	10 k	45 k	10 k	45 k
2.5 V	11 k	55 k	12 k	74 k
1.8 V	18 k	70 k	17 k	110 k
1.5 V	19 k	90 k	19 k	140 k

Notes:

1. $R_{(WEAK\ PULL\text{-}UP\text{-}MAX)} = (VCCImax – VOHspec) / I_{WEAK\ PULL\text{-}UP\text{-}MIN}$
2. $R_{(WEAK\ PULL\text{-}DOWN\text{-}MAX)} = VOLspec / I_{WEAK\ PULL\text{-}DOWN\text{-}MIN}$

Differential I/O Characteristics

Configuration of the I/O modules as a differential pair is handled by the Microsemi Designer software when the user instantiates a differential I/O macro in the design.

Differential I/Os can also be used in conjunction with the embedded Input Register (InReg), Output Register (OutReg), Enable Register (EnReg), and Double Data Rate (DDR). However, there is no support for bidirectional I/Os or tristates with these standards.

LVDS

Low-Voltage Differential Signal (ANSI/TIA/EIA-644) is a high-speed differential I/O standard. It requires that one data bit be carried through two signal lines, so two pins are needed. It also requires external resistor termination.

The full implementation of the LVDS transmitter and receiver is shown in an example in Figure 2-134. The building blocks of the LVDS transmitter–receiver are one transmitter macro, one receiver macro, three board resistors at the transmitter end, and one resistor at the receiver end. The values for the three driver resistors are different from those used in the LVPECL implementation because the output standard specifications are different.

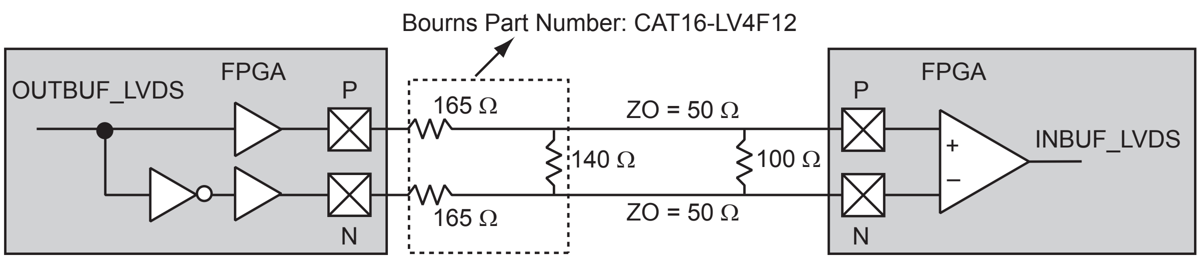

***Figure 2-134* • LVDS Circuit Diagram and Board-Level Implementation**

***Table 2-168* • Minimum and Maximum DC Input and Output Levels**

DC Parameter	Description	Min.	Typ.	Max.	Units
VCCI	Supply Voltage	2.375	2.5	2.625	V
VOL	Output Low Voltage	0.9	1.075	1.25	V
VOH	Input High Voltage	1.25	1.425	1.6	V
IOL [1]	Output Low Voltage	0.65	0.91	1.16	mA

VODIFF	Differential Output Voltage	250	350	450	mV
VOCM	Output Common Mode Voltage	1.125	1.25	1.375	V
VICM	Input Common Mode Voltage	0.05	1.25	2.35	V
VIDIFF	Input Differential Voltage	100	350		mV

Notes:

1. *IOL/IOH defined by VODIFF/(Resistor Network)*
2. *Currents are measured at 85°C junction temperature.*
3. *IIL is the input leakage current per I/O pin over recommended operation conditions where –0.3 V < VIN < VIL.*
4. *IIH is the input leakage current per I/O pin over recommended operating conditions VIH < VIN < VCCI. Input current is larger when operating outside recommended ranges.*

ISP

Fusion devices support IEEE 1532 ISP via JTAG and require a single VPUMP voltage of 3.3 V during programming. In addition, programming via a microcontroller in a target system can be achieved. Refer to the standard or the "In-System Programming (ISP) of Microsemi's Low Power Flash Devices Using FlashPro4/3/3X" chapter of the *Fusion FPGA Fabric User's Guide* for more details.

JTAG IEEE 1532

Programming with IEEE 1532

Fusion devices support the JTAG-based IEEE1532 standard for ISP. As part of this support, when a Fusion device is in an unprogrammed state, all user I/O pins are disabled. This is achieved by keeping the global IO_EN signal deactivated, which also has the effect of disabling the input buffers. Consequently, the SAMPLE instruction will have no effect while the Fusion device is in this unprogrammed state—different behavior from that of the ProASICPLUS® device family. This is done because SAMPLE is defined in the IEEE1532 specification as a noninvasive instruction. If the input buffers were to be enabled by SAMPLE temporarily turning on the I/Os, then it would not truly be a noninvasive instruction. Refer to the standard or the "In-System Programming (ISP) of Microsemi's Low Power Flash Devices Using FlashPro4/3/3X" chapter of the *Fusion FPGA Fabric User's Guide* for more details.

Boundary Scan

Fusion devices are compatible with IEEE Standard 1149.1, which defines a hardware architecture and the set of mechanisms for boundary scan testing. The basic Fusion boundary scan logic circuit is composed of the test access port (TAP) controller, test data registers, and instruction register (Figure 2-146 on page 2-230). This circuit supports all mandatory IEEE 1149.1 instructions (EXTEST, SAMPLE/PRELOAD, and BYPASS) and the optional IDCODE instruction (Table 2-185 on page 2-230).

Each test section is accessed through the TAP, which has five associated pins: TCK (test clock input), TDI, TDO (test data input and output), TMS (test mode selector), and TRST (test reset input). TMS, TDI, and TRST are equipped with pull-up resistors to ensure proper operation when no input data is supplied to them. These pins are dedicated for boundary scan test usage. Refer to the "JTAG Pins" section on page 2-226 for pull-up/-down recommendations for TDO and TCK pins. The TAP controller is a 4-bit state machine (16 states) that operates as shown in Figure 2-146 on page 2-230. The 1s and 0s represent the values that must be present on TMS at a rising edge of TCK for the given state transition to occur. IR and DR indicate that the instruction register or the data register is operating in that state.

***Table 2-184* • TRST and TCK Pull-Down Recommendations**

VJTAG	Tie-Off Resistance*
VJTAG at 3.3 V	200 Ω to 1 kΩ
VJTAG at 2.5 V	200 Ω to 1 kΩ
VJTAG at 1.8 V	500 Ω to 1 kΩ
VJTAG at 1.5 V	500 Ω to 1 kΩ

*Note: *Equivalent parallel resistance if more than one device is on JTAG chain.*

The TAP controller receives two control inputs (TMS and TCK) and generates control and clock signals for the rest of the test logic architecture. On power-up, the TAP controller enters the Test-Logic-Reset state. To guarantee a reset of the controller from any of the possible states, TMS must remain High for five TCK cycles. The TRST pin can also be used to asynchronously place the TAP controller in the Test-Logic-Reset state.

Fusion devices support three types of test data registers: bypass, device identification, and boundary scan. The bypass register is selected when no other register needs to be accessed in a device. This speeds up test data transfer to other devices in a test data path. The 32-bit device identification register is a shift register with four fields (LSB, ID number, part number, and version). The boundary scan register observes and controls the state of each I/O pin. Each I/O cell has three boundary scan register cells, each with a serial-in, serial-out, parallel-in, and parallel-out pin.

The serial pins are used to serially connect all the boundary scan register cells in a device into a boundary scan register chain, which starts at the TDI pin and ends at the TDO pin. The parallel ports are connected to the internal core logic I/O tile and the input, output, and control ports of an I/O buffer to capture and load data into the register to control or observe the logic state of each I/O.

PAC5	First contribution of a VersaTile used as a sequential module	VCC	1.5 V	0.07				µW/MHz
PAC6	Second contribution of a VersaTile used as a sequential module	VCC	1.5 V	0.29				µW/MHz
PAC7	Contribution of a VersaTile used as a combinatorial module	VCC	1.5 V	0.29				µW/MHz
PAC8	Average contribution of a routing net	VCC	1.5 V	0.70				µW/MHz
PAC9	Contribution of an I/O input pin (standard dependent)	VCCI	See Table 3-12 on page 3-18					
PAC10	Contribution of an I/O output pin (standard dependent)	VCCI	See Table 3-13 on page 3-20					
PAC11	Average contribution of a RAM block during a read operation	VCC	1.5 V	25				µW/MHz
PAC12	Average contribution of a RAM block during a write operation	VCC	1.5 V	30				µW/MHz
PAC13	Dynamic Contribution for PLL	VCC	1.5 V	2.6				µW/MHz
PAC15	Contribution of NVM block during a read operation (F < 33MHz)	VCC	1.5 V	358				µW/MHz
PAC16	1st contribution of NVM block during a read operation (F > 33 MHz)	VCC	1.5 V	12.88				mW
PAC17	2nd contribution of NVM block during a read operation (F > 33 MHz)	VCC	1.5 V	4.8				µW/MHz
PAC18	Crystal Oscillator contribution	VCC33A	3.3 V	0.63				mW
PAC19	RC Oscillator contribution	VCC33A	3.3 V	3.3				mW
PAC20	Analog Block dynamic power contribution of ADC	VCC	1.5 V	3				mW

Revision	Changes	Page
Advance 1.0 (continued)	In Table 2-47 • ADC Characteristics in Direct Input Mode, the commercial conditions were updated and note 2 is new.	2-121
	The $V_{CC33ACAP}$ signal name was changed to "XTAL1 Crystal Oscillator Circuit Input".	2-228
	Table 2-48 • Uncalibrated Analog Channel Accuracy* is new.	2-123
	Table 2-49 • Calibrated Analog Channel Accuracy [1,2,3] is new.	2-124
	Table 2-50 • Analog Channel Accuracy: Monitoring Standard Positive Voltages is new.	2-125
	In Table 2-57 • Voltage Polarity Control Truth Table—AV (x = 0), AC (x = 1), and AT (x = 3)*, the following I/O Bank names were changed: Hot-Swap changed to Standard LVDS changed to Advanced	2-131
	In Table 2-58 • Prescaler Op Amp Power-Down Truth Table—AV (x = 0), AC (x = 1), and AT (x = 3), the following I/O Bank names were changed: Hot-Swap changed to Standard LVDS changed to Advanced	2-132
	In the title of Table 2-64 • I/O Standards Supported by Bank Type, LVDS I/O was changed to Advanced I/O.	2-134
	The title was changed from "Fusion Standard, LVDS, and Standard plus Hot-Swap I/O" to Table 2-68 • Fusion Standard and Advanced I/O Features. In addition, the table headings were all updated. The heading used to be Standard and LVDS I/O and was changed to Advanced I/O. Standard Hot-Swap was changed to just Standard.	2-136
	This sentence was deleted from the "Slew Rate Control and Drive Strength" section: The Standard hot-swap I/Os do not support slew rate control. In addition, these references were changed: • From: Fusion hot-swap I/O (Table 2-69 on page 2-122) To: Fusion Standard I/O • From: Fusion LVDS I/O (Table 2-70 on page 2-122) To: Fusion Advanced I/O	2-152
	The "Cold-Sparing Support" section was significantly updated.	2-143
	In the title of Table 2-75 • Fusion Standard I/O Standards—OUT_DRIVE Settings, Hot-Swap was changed to Standard.	2-153
	In the title of Table 2-76 • Fusion Advanced I/O Standards—SLEW and OUT_DRIVE Settings, LVDS was changed to Advanced.	2-153
	In the title of Table 2-81 • Fusion Standard and Advanced I/O Attributes vs. I/O Standard Applications, LVDS was changed to Advanced.	2-157
	In Figure 2-111 • Naming Conventions of Fusion Devices with Three Digital I/O Banks and Figure 2-112 • Naming Conventions of Fusion Devices with Four I/O Banks the following names were changed: Hot-Swap changed to Standard LVDS changed to Advanced	2-160
	The Figure 2-113 • Timing Model was updated.	2-161
	In the notes for Table 2-86 • Summary of Maximum and Minimum DC Input Levels Applicable to Commercial and Industrial Conditions, T_J was changed to T_A.	2-166
