Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Spartan-II FPGA Family: Introduction and Ordering Information

DS001-1 (v2.8) June 13, 2008

Product Specification

Introduction

The Spartan®-II Field-Programmable Gate Array family gives users high performance, abundant logic resources, and a rich feature set, all at an exceptionally low price. The six-member family offers densities ranging from 15,000 to 200,000 system gates, as shown in Table 1. System performance is supported up to 200 MHz. Features include block RAM (to 56K bits), distributed RAM (to 75,264 bits), 16 selectable I/O standards, and four DLLs. Fast, predictable interconnect means that successive design iterations continue to meet timing requirements.

The Spartan-II family is a superior alternative to mask-programmed ASICs. The FPGA avoids the initial cost, lengthy development cycles, and inherent risk of conventional ASICs. Also, FPGA programmability permits design upgrades in the field with no hardware replacement necessary (impossible with ASICs).

Features

- Second generation ASIC replacement technology
  - Densities as high as 5,292 logic cells with up to 200,000 system gates
  - Streamlined features based on Virtex® FPGA architecture
  - Unlimited reprogrammability
  - Very low cost
  - Cost-effective 0.18 micron process
- System level features
  - SelectRAM™ hierarchical memory:
    - 16 bits/LUT distributed RAM
    - Configurable 4K bit block RAM
    - Fast interfaces to external RAM
  - Fully PCI compliant
  - Low-power segmented routing architecture
  - Full readback ability for verification/observability
  - Dedicated carry logic for high-speed arithmetic
  - Efficient multiplier support
  - Cascade chain for wide-input functions
  - Abundant registers/latches with enable, set, reset
  - Four dedicated DLLs for advanced clock control
  - Four primary low-skew global clock distribution nets
  - IEEE 1149.1 compatible boundary scan logic
- Versatile I/O and packaging
  - Pb-free package options
  - Low-cost packages available in all densities
  - Family footprint compatibility in common packages
  - 16 high-performance interface standards
  - Hot swap Compact PCI friendly
  - Zero hold time simplifies system timing
- Core logic powered at 2.5V and I/Os powered at 1.5V, 2.5V, or 3.3V
- Fully supported by powerful Xilinx® ISE® development system
  - Fully automatic mapping, placement, and routing

2. Discontinued by PDN2004-01.

Architectural Description

Spartan-II FPGA Array

The Spartan®-II field-programmable gate array, shown in Figure 2, is composed of five major configurable elements:

- IOBs provide the interface between the package pins and the internal logic
- CLBs provide the functional elements for constructing most logic
- Dedicated block RAM memories of 4096 bits each
- Clock DLLs for clock-distribution delay compensation and clock domain control
- Versatile multi-level interconnect structure

As can be seen in Figure 2, the CLBs form the central logic structure with easy access to all support and routing structures. The IOBs are located around all the logic and memory elements for easy and quick routing of signals on and off the chip.

Values stored in static memory cells control all the configurable logic elements and interconnect resources. These values load into the memory cells on power-up, and can reload if necessary to change the function of the device.

Each of these elements will be discussed in detail in the following sections.

Input/Output Block

The Spartan-II FPGA IOB, as seen in Figure 2, features inputs and outputs that support a wide variety of I/O signaling standards. These high-speed inputs and outputs are capable of supporting various state of the art memory and bus interfaces. Table 3 lists several of the standards which are supported along with the required reference, output and termination voltages needed to meet the standard.

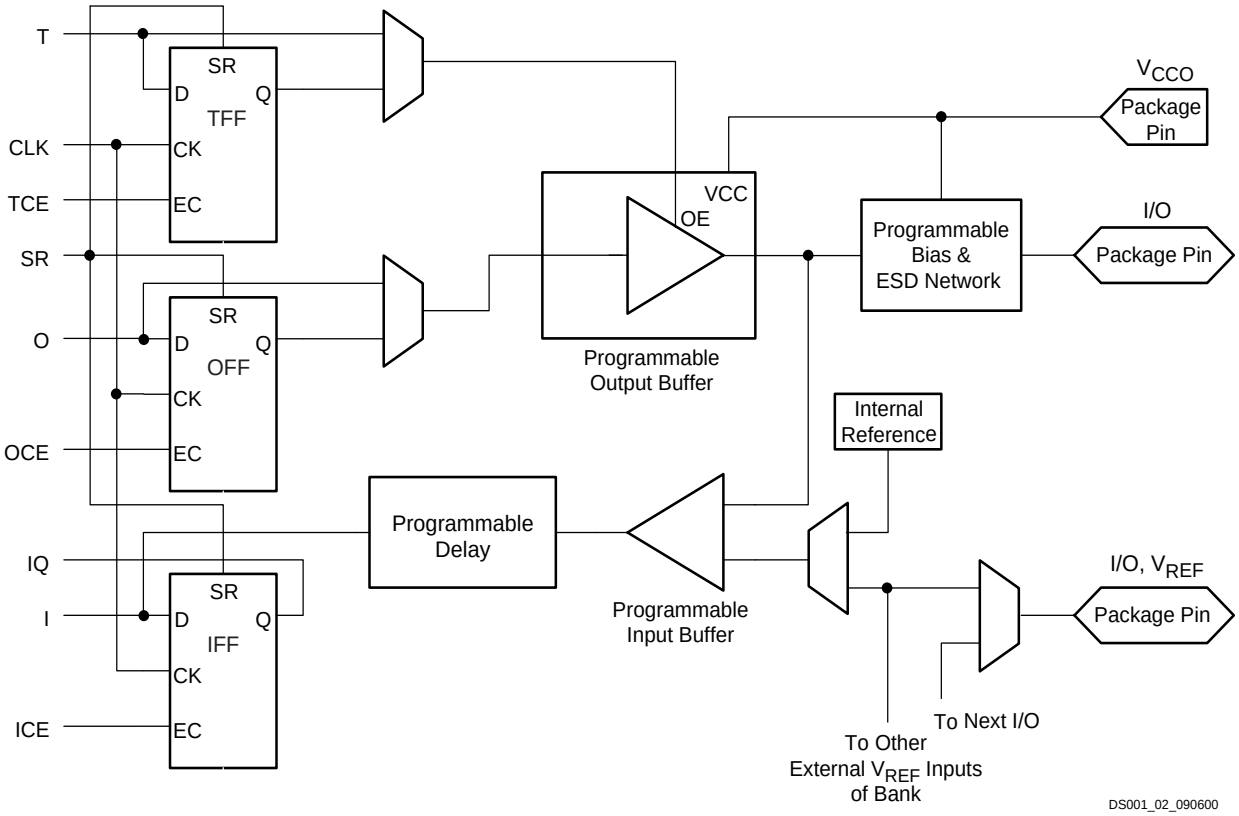

Figure 2: **Spartan-II FPGA Input/Output Block (IOB)**

Figure 9 is a diagram of the Spartan-II family boundary scan logic. It includes three bits of Data Register per IOB, the IEEE 1149.1 Test Access Port controller, and the Instruction Register with decodes.

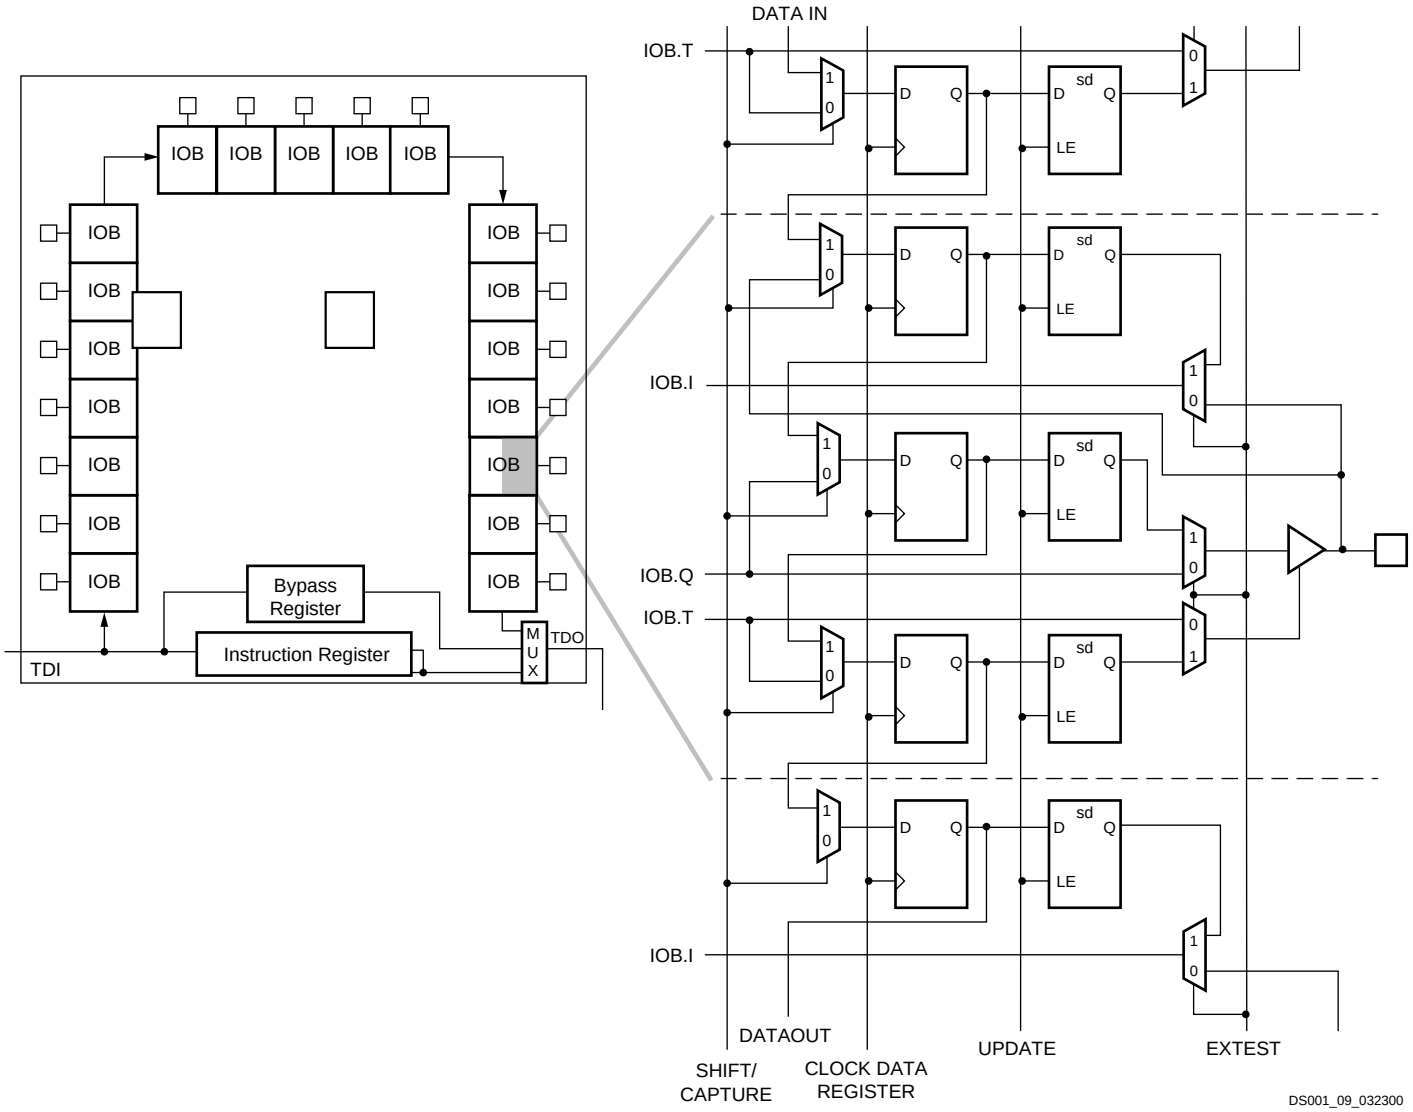

Figure 9: **Spartan-II Family Boundary Scan Logic**

Bit Sequence

The bit sequence within each IOB is: In, Out, 3-State. The input-only pins contribute only the In bit to the boundary scan I/O data register, while the output-only pins contributes all three bits.

From a cavity-up view of the chip (as shown in the FPGA Editor), starting in the upper right chip corner, the boundary scan data-register bits are ordered as shown in Figure 10.

BSDL (Boundary Scan Description Language) files for Spartan-II family devices are available on the Xilinx website, in the Downloads area.

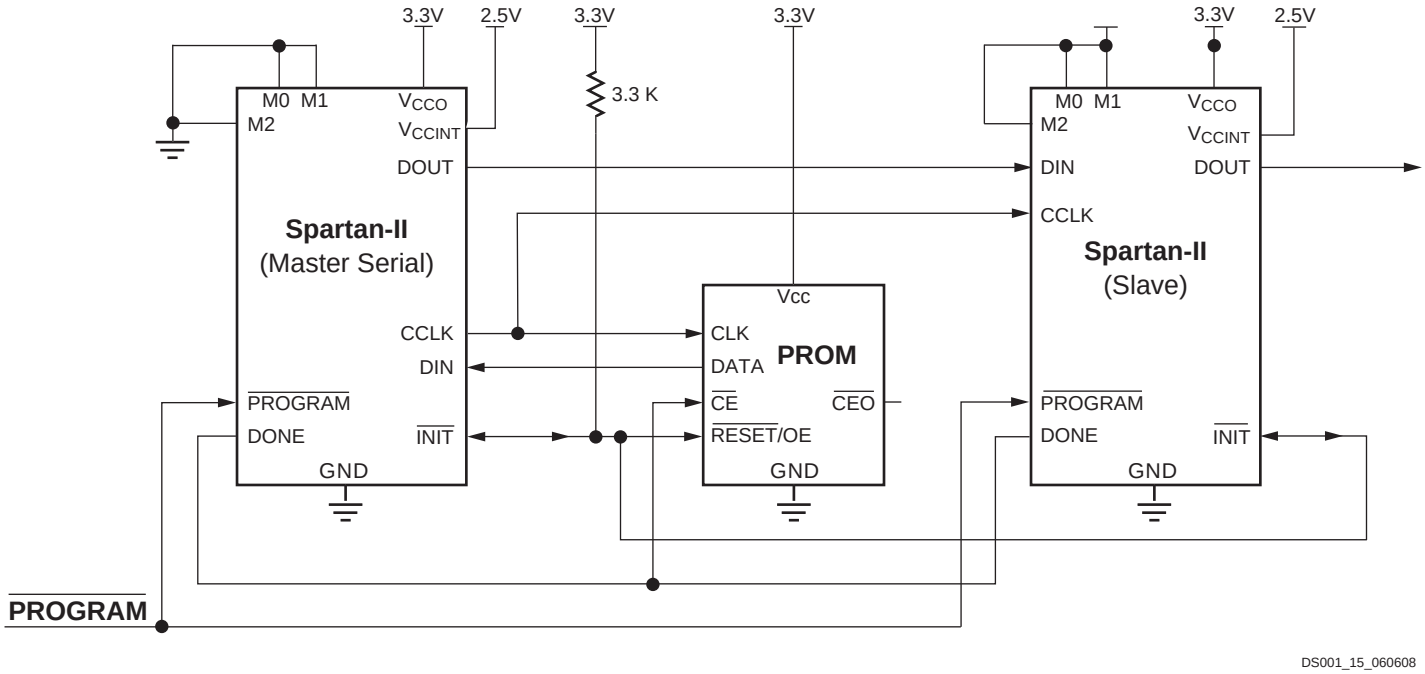
Slave Serial Mode

In Slave Serial mode, the FPGA's CCLK pin is driven by an external source, allowing FPGAs to be configured from other logic devices such as microprocessors or in a daisy-chain configuration. Figure 15 shows connections for a Master Serial FPGA configuring a Slave Serial FPGA from a PROM. A Spartan-II device in slave serial mode should be connected as shown for the third device from the left. Slave Serial mode is selected by a <11x> on the mode pins (M0, M1, M2).

Figure 16 shows the timing for Slave Serial configuration. The serial bitstream must be setup at the DIN input pin a short time before each rising edge of an externally generated CCLK.

Multiple FPGAs in Slave Serial mode can be daisy-chained for configuration from a single source. The maximum amount of data that can be sent to the DOUT pin for a serial daisy chain is 2^{20}-1 (1,048,575) 32-bit words, or 33,554,400 bits, which is approximately 25 XC2S200 bitstreams. The configuration bitstream of downstream devices is limited to this size.

After an FPGA is configured, data for the next device is routed to the DOUT pin. Data on the DOUT pin changes on the rising edge of CCLK. Configuration must be delayed until $\overline{\text{INIT}}$ pins of all daisy-chained FPGAs are High. For more information, see "Start-up," page 19.



Notes:
1. If the DriveDone configuration option is not active for any of the FPGAs, pull up DONE with a 330Ω resistor.

Figure 15: **Master/Slave Serial Configuration Circuit Diagram**

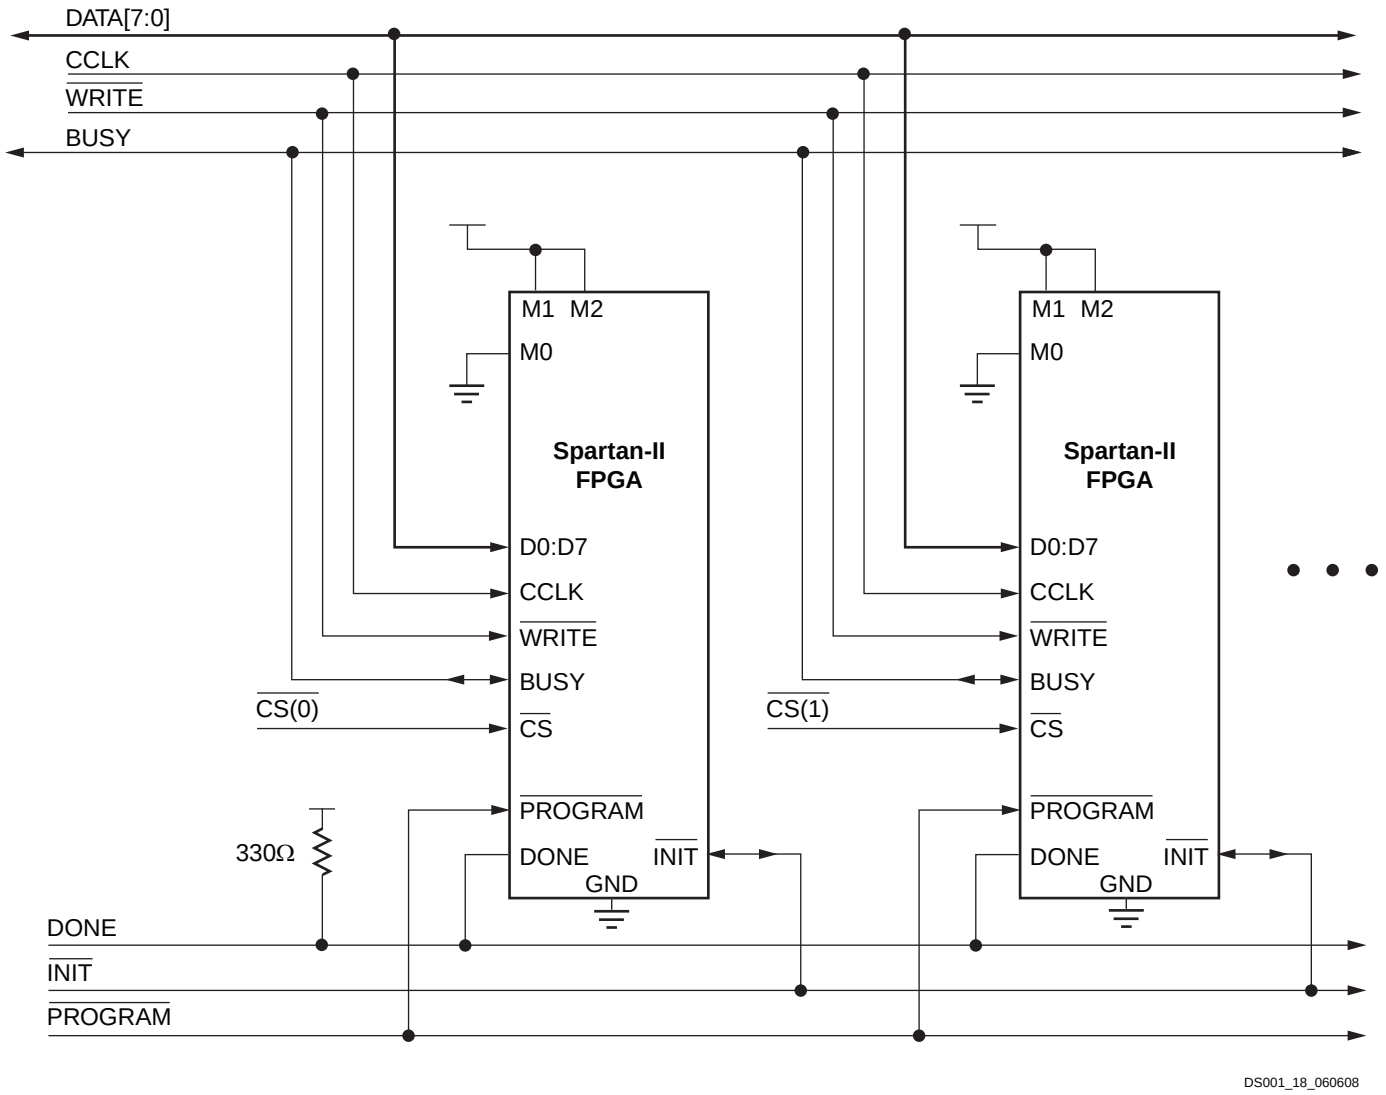


Figure 18: **Slave Parallel Configuration Circuit Diagram**

Multiple Spartan-II FPGAs can be configured using the Slave Parallel mode, and be made to start-up simultaneously. To configure multiple devices in this way, wire the individual CCLK, Data, $\overline{\text{WRITE}}$, and BUSY pins of all the devices in parallel. The individual devices are loaded separately by asserting the $\overline{\text{CS}}$ pin of each device in turn and writing the appropriate data. Sync-to-DONE start-up timing is used to ensure that the start-up sequence does not begin until all the FPGAs have been loaded. See "Start-up," page 19.

Write

When using the Slave Parallel Mode, write operations send packets of byte-wide configuration data into the FPGA. Figure 19, page 25 shows a flowchart of the write sequence used to load data into the Spartan-II FPGA. This is an expansion of the "Load Configuration Data Frames" block in Figure 11, page 18. The timing for write operations is shown in Figure 20, page 26.

For the present example, the user holds $\overline{\text{WRITE}}$ and $\overline{\text{CS}}$ Low throughout the sequence of write operations. Note that when $\overline{\text{CS}}$ is asserted on successive CCLKs, $\overline{\text{WRITE}}$ must remain either asserted or de-asserted. Otherwise an abort will be initiated, as in the next section.

1. Drive data onto D0-D7. Note that to avoid contention, the data source should not be enabled while $\overline{\text{CS}}$ is Low and $\overline{\text{WRITE}}$ is High. Similarly, while $\overline{\text{WRITE}}$ is High, no more than one device's $\overline{\text{CS}}$ should be asserted.
2. On the rising edge of CCLK: If BUSY is Low, the data is accepted on this clock. If BUSY is High (from a previous write), the data is not accepted. Acceptance will instead occur on the first clock after BUSY goes Low, and the data must be held until this happens.
3. Repeat steps 1 and 2 until all the data has been sent.
4. De-assert $\overline{\text{CS}}$ and $\overline{\text{WRITE}}$.

			Min	Min	
T_{PSDLL} / T_{PHDLL}	Input setup and hold time relative to global clock input signal for LVTTL standard, no delay, IFF,(1) with DLL	All	1.7 / 0	1.9 / 0	ns

Notes:
1. IFF = Input Flip-Flop or Latch
2. Setup time is measured relative to the Global Clock input signal with the fastest route and the lightest load. Hold time is measured relative to the Global Clock input signal with the slowest route and heaviest load.
3. DLL output jitter is already included in the timing calculation.
4. A zero hold time listing indicates no hold time or a negative hold time.
5. For data input with different standards, adjust the setup time delay by the values shown in "IOB Input Delay Adjustments for Different Standards," page 57. For a global clock input with standards other than LVTTL, adjust delays with values from the "I/O Standard Global Clock Input Adjustments," page 61.

Notes:

1. Output timing is measured at 1.4V with 35 pF external capacitive load for LVTTL. For other I/O standards and different loads, see the tables "Constants for Calculating TIOOP" and "Delay Measurement Methodology," page 60.

Calculation of T_{IOOP} as a Function of Capacitance

T_{IOOP} is the propagation delay from the O Input of the IOB to the pad. The values for T_{IOOP} are based on the standard capacitive load (C_{SL}) for each I/O standard as listed in the table "Constants for Calculating TIOOP", below.

For other capacitive loads, use the formulas below to calculate an adjusted propagation delay, T_{IOOP1}.

$$T_{IOOP1} = T_{IOOP} + Adj + (C_{LOAD} - C_{SL}) * F_L$$

Where:

- Adj is selected from "IOB Output Delay Adjustments for Different Standards", page 59, according to the I/O standard used
- C_{LOAD} is the capacitive load for the design
- F_L is the capacitance scaling factor

Notes:
1. Input timing for GPLVTTL is measured at 1.4V. For other I/O standards, see the table "Delay Measurement Methodology," page 60.

CLB Arithmetic Switching Characteristics

Setup times not listed explicitly can be approximated by decreasing the combinatorial delays by the setup time adjustment listed. Precise values are provided by the timing analyzer.

Notes:
1. A zero hold time listing indicates no hold time or a negative hold time.

Pinout Tables

The following device-specific pinout tables include all packages available for each Spartan®-II device. They follow the pad locations around the die, and include Boundary Scan register locations.
