#### What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

## 5.0 FLASH PROGRAM MEMORY

Note: This data sheet summarizes the features of the PIC32MX1XX/2XX 28/36/44-pin Family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to Section 5. "Flash Program Memory" (DS60001121), which is available from the *Documentation* > *Reference Manual* section of the Microchip PIC32 web site (www.microchip.com/pic32).

PIC32MX1XX/2XX 28/36/44-pin Family devices contain an internal Flash program memory for executing user code. There are three methods by which the user can program this memory:

- Run-Time Self-Programming (RTSP)
- EJTAG Programming
- In-Circuit Serial Programming™ (ICSP™)

RTSP is performed by software executing from either Flash or RAM memory. Information about RTSP techniques is available in **Section 5. "Flash Program Memory"** (DS60001121) in the *"PIC32 Family Reference Manual"*.

EJTAG is performed using the EJTAG port of the device and an EJTAG capable programmer.

ICSP is performed using a serial data connection to the device and allows much faster programming times than RTSP.

The EJTAG and ICSP methods are described in the *"PIC32 Flash Programming Specification"* (DS60001145), which can be downloaded from the Microchip web site.

Note: The Flash page size on PIC32MX-1XX/2XX 28/36/44-pin Family devices is 1 KB and the row size is 128 bytes (256 IW and 32 IW, respectively).

## 17.0 SERIAL PERIPHERAL INTERFACE (SPI)

Note: This data sheet summarizes the features of the PIC32MX1XX/2XX 28/36/44-pin Family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to Section 23. "Serial Peripheral Interface (SPI)" (DS60001106), which is available from the Documentation > Reference Manual section of the Microchip PIC32 web site (www.microchip.com/pic32).

The SPI module is a synchronous serial interface that is useful for communicating with external peripherals and other microcontrollers. These peripheral devices may be Serial EEPROMs, Shift registers, display drivers, Analog-to-Digital Converters (ADC), etc. The PIC32 SPI module is compatible with Motorola<sup>®</sup> SPI and SIOP interfaces. Some of the key features of the SPI module are:

- Master mode and Slave mode support
- Four clock formats
- Enhanced Framed SPI protocol support
- User-configurable 8-bit, 16-bit and 32-bit data width
- Separate SPI FIFO buffers for receive and transmit
   FIFO buffers act as 4/8/16-level deep FIFOs based on 32/16/8-bit data width
- Programmable interrupt event on every 8-bit, 16-bit and 32-bit data transfer
- · Operation during Sleep and Idle modes
- Audio Codec Support:
  - I<sup>2</sup>S protocol
  - Left-justified
  - Right-justified
  - PCM

bit 5	Master mode (MSTEN = 1):							
	1 = Input data sampled at end of data output time							
	0 = Input data sampled at middle of data output time							
	Slave mode (MSTEN = 0):							
	SMP value is ignored when SPI is used in Slave mode. The module always uses SMP = 0.							
	To write a '1' to this bit, the MSTEN value = 1 must first be written.							
bit 8	CKE: SPI Clock Edge Select bit <sup>(3)</sup>							
	1 = Serial output data changes on transition from active clock state to Idle clock state (see the CKP bit)							
	0 = Serial output data changes on transition from Idle clock state to active clock state (see the CKP bit)

	$1 = \overline{SSx}$ pin used for Slave mode							
	0 = SSx pin not used for Slave mode, pin controlled by port function.							
bit 6	<b>CKP:</b> Clock Polarity Select bit <sup>(4)</sup>							
	1 = Idle state for clock is a high level; active state is a low level							
	0 = Idle state for clock is a low level; active state is a high level							
Note 1:	When using the 1:1 PBCLK divisor, the user's software should not read or write the peripheral's SFRs in							
	the SYSCLK cycle immediately following the instruction that clears the module's ON bit.							
2:	This bit can only be written when the ON bit = $0$ .							
3:	This bit is not used in the Framed SPI mode. The user should program this bit to '0' for the Framed SPI							
	mode (FRMEN = 1).							
4:	When AUDEN = 1, the SPI module functions as if the CKP bit is equal to '1', regardless of the actual value							
	of CKP.

## 20.0 PARALLEL MASTER PORT (PMP)

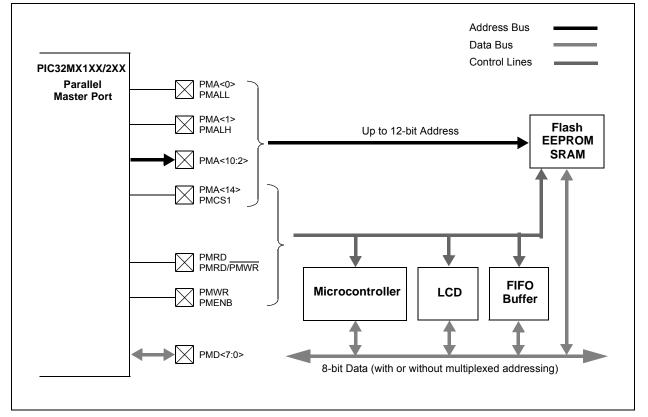

Note:	This data sheet summarizes the features of the PIC32MX1XX/2XX 28/36/44-pin Family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to Section 13. "Parallel Master Port (PMP)" (DS60001128),
	which is available from the <i>Documentation</i> > <i>Reference Manual</i> section of the Microchip PIC32 web site (www.microchip.com/pic32).

The PMP is a parallel 8-bit input/output module specifically designed to communicate with a wide variety of parallel devices, such as communications peripherals, LCDs, external memory devices and microcontrollers. Because the interface to parallel peripherals varies significantly, the PMP module is highly configurable. Key features of the PMP module include:

- Fully multiplexed address/data mode
- Demultiplexed or partially multiplexed address/ data mode
  - up to 11 address lines with single Chip Select
  - up to 12 address lines without Chip Select
- One Chip Select line
- Programmable strobe options
  - Individual read and write strobes or;
  - Read/write strobe with enable strobe
- · Address auto-increment/auto-decrement
- Programmable address/data multiplexing
- Programmable polarity on control signals
- · Legacy parallel slave port support
- · Enhanced parallel slave support
- Address support
- 4-byte deep auto-incrementing buffer

## 26.4.1 CONTROLLING CONFIGURATION CHANGES

Because peripherals can be disabled during run time, some restrictions on disabling peripherals are needed to prevent accidental configuration changes. PIC32 devices include two features to prevent alterations to enabled or disabled peripherals:

- Control register lock sequence
- · Configuration bit select lock

#### 26.4.1.1 Control Register Lock

Under normal operation, writes to the PMDx registers are not allowed. Attempted writes appear to execute normally, but the contents of the registers remain unchanged. To change these registers, they must be unlocked in hardware. The register lock is controlled by the Configuration bit, PMDLOCK (CFGCON<12>). Setting PMDLOCK prevents writes to the control registers; clearing PMDLOCK allows writes.

To set or clear PMDLOCK, an unlock sequence must be executed. Refer to **Section 6.** "**Oscillator**" (DS60001112) in the "*PIC32 Family Reference Manual*" for details.

#### 26.4.1.2 Configuration Bit Select Lock

As an additional level of safety, the device can be configured to prevent more than one write session to the PMDx registers. The Configuration bit, PMDL1WAY (DEVCFG3<28>), blocks the PMDLOCK bit from being cleared after it has been set once. If PMDLOCK remains set, the register unlock procedure does not execute, and the peripheral pin select control registers cannot be written to. The only way to clear the bit and re-enable PMD functionality is to perform a device Reset.
